# Co-ordination Chemistry of Higher Oxidation States. Part 22.1 trans-Dioxoosmium(VI) Complexes of Diamines, Diphosphines, and Diarsines

Stephen K. Harbron and William Levason\*
Department of Chemistry, The University, Southampton SO9 5NH

The reactions of tertiary arsines and diarsines with a mixture of OsO<sub>4</sub>, concentrated HCl, and ethanol at low temperatures produce the dioxo-osmium(vi) complexes [OsO<sub>2</sub>Cl<sub>2</sub>L<sub>2</sub>] (L = AsEt<sub>3</sub>, AsMe<sub>2</sub>Ph, or AsPh<sub>3</sub>) and  $[OsO_2Cl_2(L-L)][L-L = o-C_6H_4(AsMe_2)_2, o-C_6H_4(AsPh_2)_2,$ Ph, AsCH, CH, AsPh,, or Ph, AsCH=CHAsPh,]. The corresponding reactions at higher temperatures lead to mixtures containing Os<sup>VI</sup> complexes and chloro complexes of Os<sup>III</sup> and Os<sup>IV</sup>. The diphosphine complexes  $[OsO_2Cl_2(L-L)][L-L = o-C_6H_4(PMe_2)_2, Me_2PCH_2CH_2PMe_2]$ Ph,PCH,CH,PPh,, or Ph,PCH=CHPPh,] are prepared similarly, but are very difficult to obtain pure, and the bromo complexes [OsO<sub>2</sub>Br<sub>2</sub>(L-L)] (L-L = diphosphine or diarsine) are obtained from OsO<sub>4</sub>, concentrated HBr, EtOH, and L-L. NNN'N'-Tetramethylethylenediamine (tmen) produces [OsO<sub>2</sub>X<sub>2</sub>(tmen)], and [H<sub>2</sub>tmen][OsO<sub>2</sub>Cl<sub>4</sub>] has been characterised as a minor by-product in the case of  $\bar{X} = CI$ . Bis-ligand complexes  $[OsO_2(L-L)_2]^{2+}$  have been obtained only with L-L = o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)<sub>2</sub>. The complexes have been characterised by i.r., u.v.-visible, <sup>1</sup>H, and <sup>31</sup>P n.m.r. spectroscopy and microanalysis. Decomposition in solution is suggested to involve oxygen-atom transfer from the OsO<sub>2</sub><sup>2+</sup> group to the neutral ligand. The properties and stabilities of the complexes are discussed and the ease of oxidation of the neutral ligands is suggested to be a major factor determining relative stabilities.

The trans-dioxo-osmium(VI) group ('osmyl', OsO<sub>2</sub><sup>2+</sup>) is well known in mono- and di-nuclear esters and in anionic complexes such as  $[OsO_2Y_4]^{2-}$  (Y = Cl, Br, OH, CN, OMe, etc.).<sup>2</sup> Complexes with various amines are also readily prepared, including  $[OsO_2(NH_3)_4]^{2+}$ ,  $[OsO_2(H_2NCH_2CH_2NH_2)_2]^{2+}$ , and  $[OsO_2(bipy)(OH)_2]^{3-6}$  (bipy = 2,2'-bipyridyl) but examples with other donors are rare. Walton and co-workers <sup>7,8</sup> showed that the reported 'OsOCl<sub>3</sub>(PPh<sub>3</sub>)<sub>2</sub>' was a mixture of trans-[OsCl<sub>4</sub>(PPh<sub>3</sub>)<sub>2</sub>] and  $[OsO_2Cl_2(PPh_3)_2]$  and prepared other examples of the latter type with PR<sub>2</sub>Ph and PRPh<sub>2</sub> (R = alkyl) which probably have the 'all-trans' structure (I). We subsequently prepared <sup>9</sup> analogues with SMe<sub>2</sub> and SeMe<sub>2</sub> and type (II) complexes with dithioethers and diselencethers. The present paper extends this work to tertiary arsines and chelating Group 5B ligands.

## Results

trans-[OsO<sub>2</sub>Cl<sub>2</sub>(AsR<sub>3</sub>)<sub>2</sub>] (R<sub>3</sub> = Me<sub>2</sub>Ph, Ph<sub>3</sub>, or Et<sub>3</sub>).—The addition of AsEt<sub>3</sub> (2 mmol) to a mixture of OsO<sub>4</sub> (1 mmol), ethanol, and concentrated hydrochloric acid at 0 °C produces a brown solid which has the <sup>1</sup>H n.m.r. spectrum shown in the Figure. The ethyl pattern at higher frequency is characteristic <sup>10.11</sup> of the paramagnetic trans-[OsCl<sub>4</sub>(AsEt<sub>3</sub>)<sub>2</sub>], and the second set of ethyl group resonances are typical of a diamagnetic AsEt<sub>3</sub> complex. The solid also shows the strong i.r. absorption (840 cm<sup>-1</sup>) of a trans-OsO<sub>2</sub><sup>2+</sup> unit <sup>2.6,8</sup> suggesting the second species is [OsO<sub>2</sub>Cl<sub>2</sub>(AsEt<sub>3</sub>)<sub>2</sub>]. The latter is isolated pure by conducting the reaction at -50 °C. Analogues with AsPh<sub>3</sub> and AsMe<sub>2</sub>Ph were prepared, along with [OsO<sub>2</sub>Cl<sub>2</sub>-

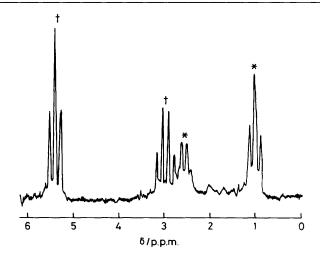

Figure. The <sup>1</sup>H n.m.r. spectrum of the product of the reaction of OsO<sub>4</sub> and AsEt<sub>3</sub> in EtOH-HCl(conc.) at 0 °C. The resonances marked (†) are assigned to *trans*-[OsCl<sub>4</sub>(AsEt<sub>3</sub>)<sub>2</sub>] and (\*) to [OsO<sub>2</sub>Cl<sub>2</sub>(AsEt<sub>3</sub>)<sub>2</sub>] (19)

(PMe<sub>2</sub>Ph)<sub>2</sub>] and the known <sup>7,8</sup> [OsO<sub>2</sub>Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] and comparison of the physical data (Table 1) shows that all have similar structures, probably the 'all-trans' form (I). Attempts to prepare the SbPh<sub>3</sub> analogue were unsuccessful. The tertiary arsine complexes are more soluble in common organic solvents, qualitatively less readily reduced than the phosphine analogues, and do not appear to be particularly light sensitive {in contrast to [OsO<sub>2</sub>Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>]}.

[OsO<sub>2</sub>X<sub>2</sub>(L-L)] (L-L = diphosphine or diarsine, X = Cl or Br).—The addition of various diarsines [L-L = o-C<sub>6</sub>H<sub>4</sub>(AsPh<sub>2</sub>)<sub>2</sub>, o-C<sub>6</sub>H<sub>4</sub>(AsMe<sub>2</sub>)<sub>2</sub>, Me<sub>2</sub>As(CH<sub>2</sub>)<sub>3</sub>AsMe<sub>2</sub>, Ph<sub>2</sub>AsCH<sub>2</sub>CH<sub>2</sub>AsPh<sub>2</sub>, or cis-Ph<sub>2</sub>AsCH=CHAsPh<sub>2</sub>] to OsO<sub>4</sub>-HCl(conc.)-EtOH mixtures (Os:L-L ratio ca. 1:1) at low temperatures, followed by thorough washing of the precipitates produced orange to brown powders,

[OsO<sub>2</sub>Cl<sub>2</sub>(L-L)]. The spectroscopic properties (Table 1), in particular the strong  $v_{asym}(OsO_2)$  vibrations in the range 830—850 cm<sup>-1</sup>, show the presence of the *trans*-OsO<sub>2</sub><sup>2+</sup> unit\* and these materials are assigned structure (II).

The synthesis of diphosphine complexes in a pure state proved to be exceptionally difficult. The addition of dichloromethane solutions of Ph2PCH2CH2PPh2, cis-Ph<sub>2</sub>PCH=CHPPh<sub>2</sub>, or o-C<sub>6</sub>H<sub>4</sub>(PPh<sub>2</sub>)<sub>2</sub> to OsO<sub>4</sub>-HCl(conc.)-EtOH mixtures at various temperatures between 0 and -50 °C produced fawn solids of rather variable analytical composition, with strong v(OsO<sub>2</sub>) and v(OsCl) modes in the i.r. spectra as expected for [OsO<sub>2</sub>Cl<sub>2</sub>(diphosphine)], but also very strong absorptions at ca. 1 100—1 200 cm<sup>-1</sup> characteristic of phosphine oxide groups.<sup>12</sup> These materials were poorly soluble in organic solvents and appear to be photochemically unstable, darkening rapidly unless kept at low temperatures in the dark. Careful control of the reaction conditions followed by washing of the precipitated solids with copious quantities of ethanol and diethyl ether produced reasonably pure samples  $[OsO_2Cl_2(L-L)]$  $(L-L = Ph_2PCH_2CH_2PPh_2)$ Ph<sub>2</sub>PCH=CHPPh<sub>2</sub>) as judged by analysis and especially by the absence of strong absorptions characteristic of P=O groups. All products obtained with  $o-C_6H_4(PPh_2)_2$  had intense v(P=O)vibrations in the i.r. spectra, and these preparations were not pursued. Similar preparations using the alkyldiphosphines Me<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PMe<sub>2</sub> and o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)<sub>2</sub> were more successful and phosphine oxide-free [OsO<sub>2</sub>Cl<sub>2</sub>(L-L)] were obtained readily, albeit in poor yield. The successful synthesis of  $[OsO_2Cl_2(Me_2PCH_2CH_2PMe_2)]$ contrasts with the failures 7,8 to obtain trialkylphosphine complexes. In separate experiments we obtained no evidence of reaction between phosphine oxide ligands, including PPh<sub>3</sub>O and Ph<sub>2</sub>P(O)CH<sub>2</sub>CH<sub>2</sub>P(O)Ph<sub>2</sub>, and OsO<sub>4</sub>-HCl(conc.)-EtOH mixtures, so it seems that the phosphine oxides found in these syntheses are present as free ligands rather than osmium(vi) complexes, a conclusion supported by the v(P=O) frequencies which were not appreciably different from those of the free ligands. Co-ordinated phosphine oxides have lower v(P=O)frequencies. 12

Replacement of the concentrated HCl by HBr in the above preparations afforded [OsO<sub>2</sub>Br<sub>2</sub>(L-L)] (L-L = diphosphine or diarsine) which have similar properties to the chloro analogues and only a few representative examples are included in Table 1. Ditertiary stibines Ph<sub>2</sub>Sb(CH<sub>2</sub>)<sub>3</sub>SbPh<sub>2</sub> or o-C<sub>6</sub>H<sub>4</sub>(SbPh<sub>2</sub>)<sub>2</sub> were chlorinated by OsO<sub>4</sub>-HCl(conc.)-EtOH mixtures, but a poor yield of the brown complex (8) was obtained with the hybrid phosphine-stibine ligand. The phenyldiphosphine complexes are poorly soluble in common organic solvents, and all of the diphosphine complexes decompose easily whilst the arsenic analogues are more readily soluble and apparently more stable.

The  ${}^{31}P$ -{ ${}^{1}H$ } n.m.r. spectra of [OsO<sub>2</sub>X<sub>2</sub>(diphosphine)] in freshly prepared dimethyl sulphoxide solutions each showed a single strong resonance in the range ca. +20 to +50 p.p.m. (relative to  $H_3PO_4$ ); the large high-frequency co-ordination shifts are characteristic of five-membered chelate rings  ${}^{13}$  and confirm structure (II). For comparison, (16) has  $\delta(P) = -21.9$  p.p.m. For (15) a single resonance at +26 p.p.m. was found, identical to that of free PPh<sub>3</sub>O showing complete decomposition of the complex. The spectra of the diphosphine complexes usually showed other weak resonances some of which could be identified as phosphine oxide or phosphonium salt impurities. The correlation of the main resonance with the [OsO<sub>2</sub>Cl<sub>2</sub>(L-L)] species was supported by exposing the solutions to bright

sunlight, when the resonance rapidly decreased consistent with the photochemical instability of these Os<sup>VI</sup> complexes. The 'impurity' signals grew somewhat in intensity as a result of this decomposition, but most of the decomposition products did not appear in the 31P n.m.r. spectra suggesting that paramagnetic Os<sup>IV</sup> or Os<sup>III</sup> are the main products. trans-[OsCl<sub>4</sub>(PR<sub>3</sub>)<sub>2</sub>] give sharp but greatly shifted (ca. 1 200 p.p.m.) <sup>31</sup>P n.m.r. spectra, <sup>10</sup> but we have not observed similar spectra for [OsCl4(diphosphine)] presumably due to unfavourable relaxation times.14 This limited solution stability frustrated attempts to record <sup>17</sup>O n.m.r. spectra but we re-examined our previously reported 9  $[OsO_2Cl_2(SeMe_2)_2]$  and  $[OsO_2Cl_2(MeSeCH_2CH_2SeMe)]$  by  $^{77}$ Se n.m.r. spectroscopy. The latter showed two resonances at  $\delta$ 337.4 and 328.9 p.p.m. (relative to SeMe<sub>2</sub>) consistent with the presence of meso and DL invertomers, the shifts being similar to those of MeSeCH<sub>2</sub>CH<sub>2</sub>SeMe chelated to other platinum metals.15 The solution obtained from [OsO<sub>2</sub>Cl<sub>2</sub>(SeMe<sub>2</sub>)<sub>2</sub>] showed a single resonance at  $\delta$  808 p.p.m. in the  $^{77}\text{Se}$  n.m.r. spectrum, not consistent with co-ordinated SeMe<sub>2</sub> but indicative of SeMe<sub>2</sub>O (lit., <sup>16</sup> 812 p.p.m.), analogous to the result observed in the production of PPh<sub>3</sub>O from the triphenylphosphine complex.

The electronic spectra of the  $[OsO_2X_2(L-L)]$  complexes (Table 1) are dominated by intense absorptions at > ca. 24 000 cm<sup>-1</sup> due to L $\rightarrow$ Os charge-transfer transitions, and weaker absorptions or shoulders to lower energy may be the d-d transitions expected for  $d^2$  Os<sup>VI</sup>. Diffuse reflectance (d.r.) spectra are similar in profile to the solution spectra although with poorly defined peak maxima. In view of the solution instability the  $\varepsilon_{mol}$  values in Table 1 should be treated as approximate only, although repetitive scanning of some spectra showed decomposition to be slow over the time taken. All the complexes are diamagnetic, as expected for trans-OsO<sub>2</sub><sup>2+</sup> groups where the strong  $O_{p\pi} \longrightarrow Os_{d\pi}$  interactions produce a  $d_{xy}^2$  ground state. 17

Chemically these [OsO<sub>2</sub>X<sub>2</sub>(L-L)] complexes are readily converted to [OsX<sub>4</sub>(L-L)] by heating with HX in aqueous ethanol, although the latter are more readily prepared from [OsX<sub>6</sub>]<sup>2-14</sup> The [OsO<sub>2</sub>X<sub>2</sub>(PR<sub>3</sub>)<sub>2</sub>] complexes have been shown to be useful starting materials for the preparation of high-valent osmium complexes (see refs. 7, 8, and 18, for example) and the mono- and di-arsine complexes reported here may be similarly valuable. The difficulty of preparing pure samples of the diphosphine complexes (and the poor yields) makes them less attractive in this respect.

 $[OsO_2\{o-C_6H_4(PMe_2)_2\}_2]X_2[X=Cl(21)\ or\ Br(22)]$ .—We found that addition of excess  $o-C_6H_4(PMe_2)_2$  to  $OsO_4$ —HCl(conc.)—EtOH produced a fawn solid of composition  $[OsO_2\{o-C_6H_4(PMe_2)_2\}_2]Cl_2$  (21) with  $v(OsO_2)$  841 cm<sup>-1</sup>, very similar to that of  $[OsO_2Cl_2\{o-C_6H_4(PMe_2)_2\}]$  (843 cm<sup>-1</sup>), but whereas the latter has a strong v(OsCl) at ca. 322 cm<sup>-1</sup>, the former has only weak absorption in the range 350—300 cm<sup>-1</sup>. If HBr is used in place of HCl, (22) is formed with an identical i.r. spectrum to that of the chloride. The bromide is however unstable in solution.

o-Phenylenebis(dimethylphosphine) has a pronounced tendency to form 2:1 complexes with many transition metals, <sup>19</sup> but the production of  $[OsO_2(L-L)_2]^{2+}$  was unexpected. Attempts to obtain  $[OsO_2(Me_2PCH_2CH_2PMe_2)_2]^{2+}$  gave only the 1:1 complex (3), whilst reaction of a  $OsO_4$ -EtOH-HBF<sub>4</sub> mixture with  $Me_2PCH_2CH_2PMe_2$  at 0 °C in an attempt to form  $[OsO_2(Me_2PCH_2CH_2PMe_2)_2][BF_4]_2$  instantly produced a black osmium oxide. The reaction of  $OsO_4$ -HCl(conc.)-EtOH with excess  $o-C_6H_4(AsMe_2)_2$  afforded a pink solid which had a strong  $v_{asym}(OsO_2)$  at 858 cm<sup>-1</sup> and analysed as a complex with L-L:Os ca. 2:1. However the u.v.-visible spectrum showed the characteristic features of  $trans-[OsCl_2\{o-C_6H_4-1\}]$ 

<sup>\*</sup> Various attempts to record Raman spectra gave indifferent results with instant blackening of the samples, not surprising in view of the light sensitivity of some of these materials.

(AsMe<sub>2</sub>)<sub>2</sub>]<sub>2</sub>]Cl <sup>14,20</sup> which is responsible for the unusual pink colour. Our data suggest  $[OsO_2\{o-C_6H_4(AsMe_2)_2\}_2]Cl_2$  is formed in this reaction, but is too unstable to separate from the reduction product [OsCl<sub>2</sub>{o-C<sub>6</sub>H<sub>4</sub>(AsMe<sub>2</sub>)<sub>2</sub>}<sub>2</sub>]Cl.

 $trans-[OsO_2(en), ]Cl_2(20)$  (en = ethylenediamine) has been reported previously,<sup>3</sup> and the cation characterised (as the HSO<sub>4</sub> salt) by a single crystal X-ray study.<sup>21</sup> Spectroscopic data on this are included in Table 1 for comparison.

Diamine Complexes.—None of the phosphine or arsine complexes produced above yielded crystals suitable for an Xray study, and in the hope of obtaining more tractable materials we investigated N-alkylated diamine complexes. The addition of NNN'N'-tetramethylethylenediamine (tmen) to HCl(conc.)-EtOH resulted in black precipitates, presumably osmium oxides. However addition of tmen-2HCl to an aqueous solution of potassium osmate(vi), K<sub>2</sub>[OsO<sub>2</sub>(OH)<sub>4</sub>] (cf. ref. 3), readily afforded an orange-brown powder [OsO<sub>2</sub>Cl<sub>2</sub>(tmen)]. The bromo analogue was obtained from tmen-2HBr, but this reaction fails with o-C<sub>6</sub>H<sub>4</sub>(NMe<sub>2</sub>)<sub>2</sub>·2HCl. Excess amine hydrochloride failed to give 2:1 complexes {and conversely a 1:1 ratio of en·2HCl: K<sub>2</sub>[OsO<sub>2</sub>(OH)<sub>4</sub>] still produced (20)].

The  $[OsO_2X_2(tmen)]$  complexes are rather stable powders but disappointingly have poor solubility in organic solvents or water, and attempts to grow single crystals in situ were made. Most failed, producing powdered [OsO<sub>2</sub>X<sub>2</sub>(tmen)], but one gave a few small crystals. A single-crystal X-ray study showed <sup>22</sup> these to be [H<sub>2</sub>tmen][OsO<sub>2</sub>Cl<sub>4</sub>]. Since subsequent studies showed that even in the presence of excess HX, [OsO<sub>2</sub>X<sub>2</sub>(tmen)] were the major products it seems likely that [H<sub>2</sub>tmen]-[OsO<sub>2</sub>Cl<sub>4</sub>] is a minor by-product or hydrolysis product. We note that [Pt(tmen)( $\eta^2$ -C<sub>2</sub>H<sub>4</sub>)Cl]<sup>+</sup> in concentrated aqueous HCl gave [Pt(tmen)Cl<sub>2</sub>] and [Pt(Htmen)Cl<sub>3</sub>] with minor amounts of [H<sub>2</sub>tmen][PtCl<sub>4</sub>] and [H<sub>2</sub>tmen][PtCl<sub>6</sub>], the proportion of the [H<sub>2</sub>tmen]<sup>2+</sup> salts increasing with longer reaction times.<sup>23</sup> The i.r. spectrum of [H<sub>2</sub>tmen][OsO<sub>2</sub>Cl<sub>4</sub>] has v(OsO<sub>2</sub>) 847 and v(OsCl) 298 cm<sup>-1</sup>, in good agreement with Cs<sub>2</sub>[OsO<sub>2</sub>Cl<sub>4</sub>] (845 and 308 cm<sup>-1</sup> respectively),<sup>9</sup> and clearly different from that of (1) (Table 1).

#### Discussion

The complexes reported here and those of the type  $[OsO_2X_2L_2]$  $(X = Cl \text{ or } Br; L = PR_3, SR_2, etc.)$  described elsewhere <sup>7-9</sup> are

rare examples of heavy Group 5B and 6B donors bound to a transition metal centre of very high formal oxidation state (Os<sup>VI</sup>). The only other examples of M<sup>VI</sup> species are the nitrido complexes  $[Os(N)X_3(ER_3)_2]$  and  $[Ru(N)X_3(ER_3)_2]^{24}$  (E = P,As, or Sb) and a few tungsten(vi) complexes, including [WOCl<sub>4</sub>{o-C<sub>6</sub>H<sub>4</sub>(AsMe<sub>2</sub>)<sub>2</sub>}],<sup>25</sup> SMe)],<sup>26</sup> and [WCl<sub>6</sub>(SMe<sub>2</sub>)].<sup>27</sup> [(WSCl<sub>4</sub>)<sub>2</sub>(MeSCH<sub>2</sub>CH<sub>2</sub>-

The isolated dioxo-osmium(vi) complexes are all rather unstable and qualitatively this stability varies with halide as expected (Cl > Br) but with the neutral donors the order is unusual (S > As  $\sim$  Se > P). Thio- and seleno-ethers are usually less able to bond effectively to high-oxidation-state metal centres than are phosphines and arsines. 15,19,28 The formation of  $[OsO_2\{o-C_6H_4(PMe_2)_2\}_2]^{2+}$  by this diphosphine alone can be viewed as a successful competition of the second diphosphine molecule with halide for the osmium, and seems more in keeping with the expected donor ability. In fact the observed 'stability' order with neutral ligands reflects the ease of oxidation of the free ligands, and indicates that in these systems there is a competition between complexation and oxidation of the neutral ligand by the osmium(vi). The SR<sub>2</sub> and AsR<sub>3</sub> are less easily oxidised than SeR2 or PR3 which accounts for the easier preparation and better yields of complexes of the former ligands, and the greater apparent stability once isolated. Our successful preparation of [OsO<sub>2</sub>Cl<sub>2</sub>(Me<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PMe<sub>2</sub>)] contrasted with the failure 8 to obtain [OsO<sub>2</sub>Cl<sub>2</sub>(PR<sub>3</sub>)<sub>2</sub>] (R = alkyl) supports this argument since the chelating ligand will produce less labile complexes.

The decomposition products of  $[OsO_2Cl_2L_2][L = PPh_3]$  or SeMe<sub>2</sub>], identified as PPh<sub>3</sub>O and SeMe<sub>2</sub>O, indicates that decomposition may involve direct attack of the neutral ligand on the osmyl oxygen. Such oxygen-atom transfer reactions are well documented for a variety of high-valent M=O species. 29-31 The analogy with the study of Pawson and Griffith 24 on  $[OsNCl_4]^- + L$  systems should be noted;  $[OsNCl_3L_2]$  (L = AsR<sub>3</sub> or SbR<sub>3</sub>) can be isolated directly whereas PR<sub>3</sub> ligands bring about reduction to the OsIV phosphine imidates [Os(NPR<sub>3</sub>)Cl<sub>3</sub>(PR<sub>3</sub>)<sub>2</sub>]. These phosphine imidate moieties are analogous to the OsOPR3 intermediates assumed but rarely detected in the oxo systems [see, however, ref. 30 for an Ru(OPR<sub>3</sub>) intermediate].

#### **Experimental**

Physical measurements were made as described in previous parts of this series. Osmium analyses were performed as described.9 The phenyldiphosphine complexes gave low and poorly reproducible analyses by this method which appear to result from difficulty in completely destroying the ligands without some loss of OsO<sub>4</sub>. Similar problems have been reported in other systems. Analytical data are given in Table 2.

[OsO<sub>2</sub>Cl<sub>2</sub>(Ph<sub>2</sub>AsCH=CHAsPh<sub>2</sub>)] (12).—To a solution of OsO<sub>4</sub> (0.099 g, 0.39 mmol) in a mixture of ethanol (3 cm<sup>3</sup>) and concentrated hydrochloric acid (0.5 cm<sup>3</sup>) was added Ph<sub>2</sub>AsCH=CHAsPh<sub>2</sub> (0.192 g, 0.40 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (1 cm<sup>3</sup>) dropwise via a syringe at 0 °C. The mixture was stirred for ca. 10 min after which time an orange-brown powder had deposited. This was collected and washed with ethanol (3  $\times$  10 cm<sup>3</sup>) and diethyl ether (2  $\times$  10 cm<sup>3</sup>) and dried in vacuo (0.18 g,

The complexes (13) and (10) were prepared by an analogous route. The complexes (5) and (6) were similarly made except that the reactions were carried out in darkness and products carefully washed with CH2Cl2 before any spectroscopic or analytical data were obtained.

<sup>&</sup>lt;sup>a</sup> Calculated values are in parentheses. <sup>b</sup> N or Os. <sup>c</sup> Nitrogen. <sup>d</sup> Osmium.

[OsO<sub>2</sub>Cl<sub>2</sub>(tmen)] (1).—K<sub>2</sub>[OsO<sub>2</sub>(OH)<sub>4</sub>] prepared from KOH(aq)—OsO<sub>4</sub>—EtOH was dissolved in water. An excess of tmen-2HCl was prepared from tmen and concentrated hydrochloric acid, and dissolved in water. The two solutions were combined resulting in a copper coloured solution. After leaving for 24 h at 0 °C, orange-brown crystals had been deposited which were isolated by filtration, washed with copious quantities of diethyl ether, and dried *in vacuo*. Complex (2) was similarly prepared using concentrated HBr.

[OsO<sub>2</sub>Cl<sub>2</sub>(Me<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PMe<sub>2</sub>)] (3).—Osmium tetraoxide (0.220 g, 0.87 mmol) was dissolved in EtOH–HCl(ca. 10:1 v/v) (8 cm<sup>3</sup>). This mixture was purged with nitrogen and cooled to 0 °C. Me<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PMe<sub>2</sub> (0.150 g, 1.00 mmol) was added dropwise to this mixture giving a tan precipitate. The mixture was then stirred in the dark for ca. 10 min. The tan solid was then collected and washed with ethanol (3 × 10 cm<sup>3</sup>) and diethyl ether (3 × 10 cm<sup>3</sup>) and dried *in vacuo*. Complex (4) was prepared by a similar route.

[OsO<sub>2</sub>Cl<sub>2</sub>{o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)<sub>2</sub>}] (7).—Osmium tetraoxide (0.236 g, 0.93 mmol) was dissolved in EtOH–HCl(ca. 10:1 v/v) (8 cm<sup>3</sup>). This mixture was purged with nitrogen and o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)<sub>2</sub> (0.190 g, 0.96 mmol) was added dropwise, via a syringe, over a period of a few minutes at room temperature. The light brown solid deposited was collected, washed with ethanol (3 × 10 cm<sup>3</sup>) and diethyl ether (3 × 10 cm<sup>3</sup>), and dried in vacuo.

[OsO<sub>2</sub>Cl<sub>2</sub>{o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)(SbMe<sub>2</sub>)}] (8).—To a nitrogen-purged mixture of OsO<sub>4</sub> (0.217 g, 0.85 mmol) dissolved in EtOH–HCl(ca. 10:1 v/v) (8 cm³), cooled to 0 °C, was added o-C<sub>6</sub>H<sub>4</sub>(PMe<sub>2</sub>)(SbMe<sub>2</sub>) (0.395 g, 1.40 mmol) dropwise via a syringe over a period of 5 min. The mixture was then stirred in darkness for 30 min during which time a brown solid was deposited. This was collected, washed with ethanol (3 × 15 cm³) and diethyl ether (3 × 15 cm³), and dried *in vacuo* (0.05 g, 10%). Prior to obtaining analytical data the product was carefully washed with dichloromethane–diethyl ether to remove any oxidised ligand or decomposition products.

 $[OsO_2Cl_2\{o-C_6H_4(AsMe_2)_2\}]$  (9).—Osmium tetraoxide (0.092 g, 0.36 mmol) was dissolved in EtOH-HCl(ca. 10:1 v/v) (2 cm³), purged with nitrogen, and cooled to ca. -50 °C in a slush bath. o-C<sub>6</sub>H<sub>4</sub>(AsMe<sub>2</sub>)<sub>2</sub> (0.103 g, 0.36 mmol) was added dropwise via a syringe. The mixture was stirred and allowed to warm to 0 °C over a period of ca. 40 min. During this time a dark brown solid was deposited which was isolated using a fritstick under nitrogen, washed with nitrogen-purged ethanol (2 × 5 cm³) and diethyl ether (2 × 5 cm³), and dried in vacuo.

[OsO<sub>2</sub>Cl<sub>2</sub>(Ph<sub>2</sub>AsCH<sub>2</sub>CH<sub>2</sub>AsPh<sub>2</sub>)] (11).—To a mixture of OsO<sub>4</sub> (0.072 g, 0.28 mmol) dissolved in EtOH–HCl(ca.10:1 v/v) (3 cm<sup>3</sup>) was added Ph<sub>2</sub>AsCH<sub>2</sub>CH<sub>2</sub>AsPh<sub>2</sub> (0.136 g, 0.28 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (1 cm<sup>3</sup>) over a period of 5 min at room temperature. The mixture was then placed in ice at 0 °C for 30 min and a brown solid was produced. This was isolated, washed with ethanol (2 × 10 cm<sup>3</sup>) and diethyl ether (2 × 10 cm<sup>3</sup>), and dried *in vacuo* (0.057 g, 25%).

 $[OsO_2Cl_2\{Me_2As(CH_2)_3AsMe_2\}]$  (14).—Osmium tetra-oxide (0.065 g, 0.26 mmol) was dissolved in EtOH-HCl(ca. 10:1 v/v) (2 cm³). This mixture was purged with nitrogen prior to dropwise addition of  $Me_2As(CH_2)_3AsMe_2$  (0.080 g, 0.32 mmol) at ca. -50 °C. The mixture was stirred and gradually allowed to warm to ca. -20 °C under nitrogen. At this point a buff solid had been deposited which was collected under nitrogen, washed with deoxygenated diethyl ether (15 cm³), and dried in vacuo. The complexes (18) and (19) were prepared by a similar route.

 $[OsO_2Cl_2(PMe_2Ph)_2]$  (16).—Dimethylphenylphosphine (0.356 g, 2.78 mmol) was added dropwise to a stirred, nitrogenpurged solution of  $OsO_4$  (0.237 g, 0.93 mmol) dissolved in EtOH–HCl(ca. 10:1 v/v) (8 cm³) over a period of 5 min; this produced a red solution. The mixture was then stirred in the dark for ca. 4 h. An orange-brown powder was precipitated, isolated by filtration, washed with ethanol (2 × 10 cm³) and diethyl ether (2 × 10 cm³), and dried in vacuo.

[OsO<sub>2</sub>Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (15).—To a stirred solution of OsO<sub>4</sub> (0.234 g, 0.92 mmol) dissolved in EtOH–HCl(ca. 10:1 v/v) was added PPh<sub>3</sub> (0.500 g, 1.91 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 cm<sup>3</sup>) over a period of 10 min. A light tan powder was deposited which was isolated, washed with ethanol (2 × 10 cm<sup>3</sup>) and diethyl ether (2 × 10 cm<sup>3</sup>), and dried *in vacuo*. Prior to obtaining analytical data the solid was washed with copious quantities of dichloromethane and dried *in vacuo* to remove any soluble decomposition products. The AsPh<sub>3</sub> analogue (17) was prepared by a similar route.

 $[OsO_2\{o-C_6H_4(PMe_2)_2\}_2]Br_2$  (22). To a nitrogen-purged mixture of  $OsO_4$  (0.189 g, 0.74 mmol) dissolved in EtOH–HBr(ca. 10:1 v/v) (8 cm³) was added an excess of o- $C_6H_4(PMe_2)_2$  (0.36 g, 1.8 mmol) at 0 °C. The mixture immediately gave a fawn powder which was isolated after ca. 20 min, washed with ethanol (3 × 15 cm³) and diethyl ether (3 × 10 cm³), and dried in vacuo. The chloride analogue (21) was similarly made using concentrated hydrochloric acid.

Complex (20) was prepared by the method of Malin and Taube.<sup>3</sup>
