2-Methyl *N*-(*p*-Toluenesulfinyl)aziridine-2-carboxylic Acid: Asymmetric Synthesis of α-Methylphenylalanine and α-Methyl-β-phenylserine

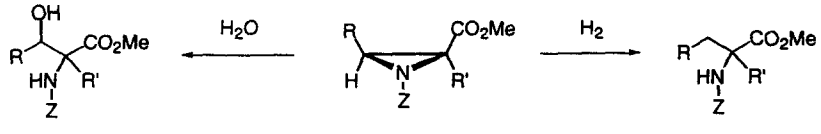
Franklin A. Davis,* Hu Liu, and G. Venkat Reddy
Department of Chemistry, Temple University, Philadelphia, PA 19122-2585

Summary: 2-Substituted aziridine **2a**, prepared from sulfinimine **1** via a Darzens-type condensation, undergoes a highly regio- and stereocontrolled ring-opening to give α-methylphenylalanine and α-methyl-β-phenylserine in high enantiomeric purity. Copyright © 1996 Elsevier Science Ltd

The high level of interest in α-alkylated α-amino acids[1] stems from their biological stability,[2] their utility in studies of enzyme mechanisms,[3] and their use as enzyme inhibitors.[4] Furthermore, once incorporated into peptides, these amino acids influence the conformation of the protein, thereby altering its properties.[5] Most of the methods developed for the enantioselective syntheses of the α-alkylated α-amino acids[1c] involve the alkylation of chiral nonracemic enolates derived from β-lactams,[6] bis-lactims,[7] oxazinones,[8] imidazolidinones,[9] oxazaborolidinone,[10] alanine dianions[11] and other methods.[12] The direct α-alkylation of alanine and phenylalanine enolates in good to excellent ee's has also been described.[13]

N-Activated aziridine-2-carboxylic acids are playing increasingly important roles in strategies for the asymmetric synthesis of proteinogenic and nonproteinogenic α-amino acids because they undergo highly regio- and stereocontrolled ring-opening with nucleophiles (Scheme 1).[14,15] However, the only report of their application to the asymmetric synthesis of α-alkylated α-amino acids is the conversion of 2-methyl aziridine-2-carboxylic acid, prepared in several steps from an optically active oxirane, to α-methyl cysteine derivatives.[16] That there are so few aziridine mediated syntheses of α-alkylated α-amino acids is undoubtedly due to the lack of convenient routes to these heterocycles.[17] In this letter we report methodology for the enantioselective synthesis of 2-substituted aziridine-2-carboxylic acids and their application to the asymmetric synthesis of α-alkyl-α-amino acid derivatives.

Scheme 1

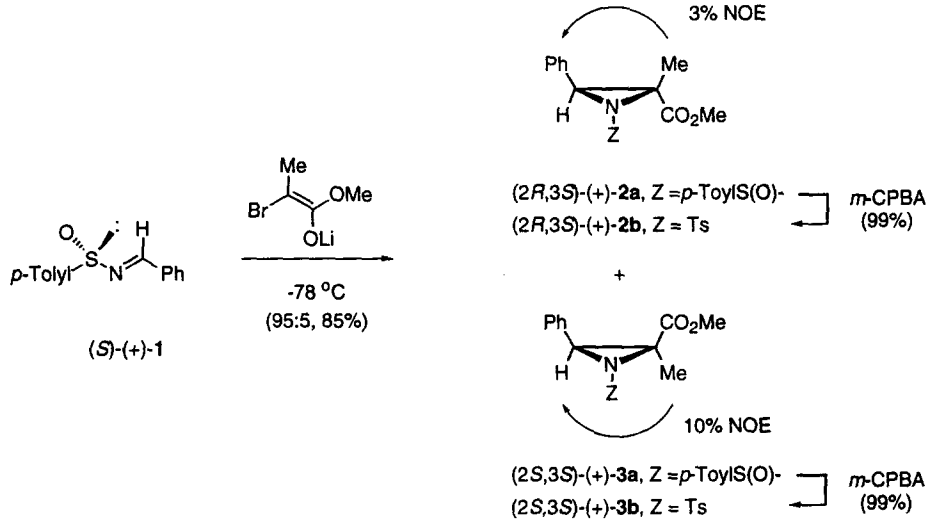


Z =Activating group

Earlier studies from these laboratories reported the application of *cis*-*N*-sulfinylaziridine 2-carboxylic acids in the asymmetric synthesis of α-amino acids, β-hydroxy α-amino acids,[15] the antibiotic thiamphenacol,[18] the

antitumor agent (*R*)-(–)-dysidazirine,[19] and D-*erythro* and L-*threo*-sphingosine.[20] The requisite aziridines were prepared in modest yield via a Darzens-type synthesis involving the addition of the lithium enolate of methyl α-bromoacetate to enantiopure sulfinimines (thiooxime S-oxides). As an extension of this protocol we prepared trans-(2*R*,3*S*)-(+)-*N*-(*p*-toluenesulfinyl)-2-methyl-2-carbomethoxy-3-phenylaziridine (**2**) by treatment of (*S*)-(+)-benzylidene-*p*-toluenesulfinamide (**1**)[21] with the lithium enolate of methyl α-bromopropionate. Thus, methyl α-bromopropionate (11.1 mmol) was treated with an equivalent amount of lithium bis(trimethylsilylamide) in THF at -78 °C. After 30 min., a solution of 4.1 mmol of (+)-**1** was added to the enolate at -78 °C via cannula (Scheme 2). After 1 h the reaction mixture was quenched by addition of H_2O. The ratio of (2*R*,3*S*)-(+)-**2a**/(2*S*,3*S*)-(+)-**3a** was 95:5. Products were isolated by flash chromatography (EtOAc:*n*-pentane, 20:80) affording (2*R*,3*S*)-(+)-**2a** ($[\alpha]^{20}_D$ +99.6 (c 0.22, $CHCl_3$)) in better than 84% yield and the minor aziridine, (2*S*,3*S*)-(+)-**3a** ($[\alpha]^{20}_D$ +23.4 (c 0.95, $CHCl_3$)), in 2-3% yield. It is worth noting that higher yields of **2** (84%) for the propionate enolate are better than for the corresponding acetate enolate (65%),[15] presumably due to greater enolate stability in the former case. It proved difficult to establish the relative configurations of the N-sulfinylaziridines by NOE experiments because they exist as syn and anti mixtures. Treatment of **2a/3a** with 2 equivalents of *m*-chloroperbenzoic acid (*m*-CPBA) readily afforded the corresponding N-tosyl aziridines **2b/3b** in near quantitative yield which exist as single isomers. The fact that irradiation of the Me protons in **2b/3b** produces NOE enhancements of 3 and 10 percent in the C-3 phenyl and C-3 hydrogen, respectively, is consistent with the anti nature of the groups in (2*R*,3*S*)-(+)-**2b** ($[\alpha]^{20}_D$ +44.14 (c 0.28, $CHCl_3$)).

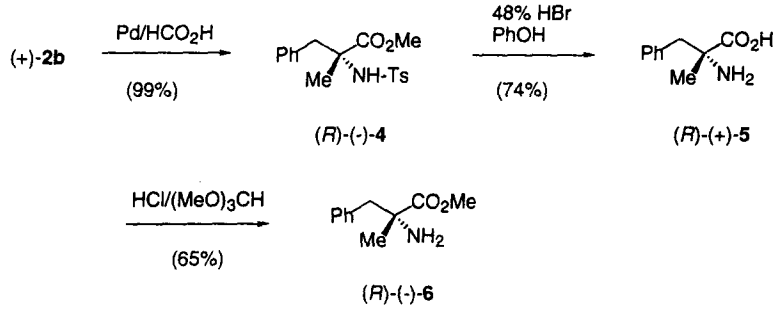
Scheme 2



Aziridine ring opening requires activation at nitrogen and N-tosyl activation often affords superior reactivity and selectivity. As noted earlier this key aziridine activating group is readily installed simply by oxidation of the N-sulfinyl aziridine.[15] Hydrogenation of (+)-**2b** gave a quantitative yield of the α-methylphenylalanine derivative (-)-**4** and was accomplished by treatment with Pd(black)/HCO_2H in ethanol for 8 h at rt and then for 1.5 h at 75 °C (Scheme 3). If the reaction was carried out from the beginning at 75 °C there

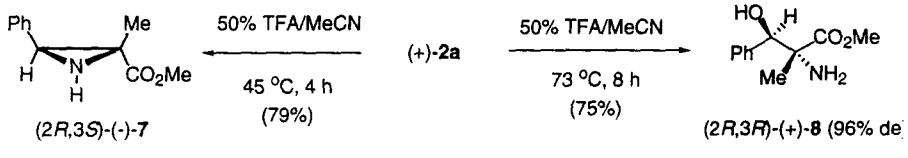
was only 68% yield of (-)-**4** after 4 days. This suggests that precomplexation of the substrate with the catalyst is required prior to hydrogenation and is hampered at the elevated temperature. Refluxing (-)-**4** with 48% HBr and phenol efficiently removed the N-tosyl group to give an 74% isolated yield of (*R*)-(+)-α-methylphenylalanine (**5**) [$[\alpha]^{20}_D$ +19.01 (c 0.51, H_2O), lit.[12d] $[\alpha]^{20}_D$ +20.5 (c 1.0, H_2O)] following isolation by ion exchange (Dowex 50x8-100, acid).[21] To further establish the enantiomeric purity of (+)-**5** it was converted to the methyl ester **6** in 65% yield according to the method of Jain.[23] Chiral shift reagent experiments with Eu(hfc)$_3$ indicate that (-)-methyl α-methylphenylalanine (**6**) ($[\alpha]^{20}_D$ -2.4 (c 0.75, EtOH)) is >95% enantiomerically pure.[24]

Scheme 3



An important advantage of the *N*-sulfinyl auxiliary is that it is easily removed under acid or base conditions thus providing the opportunity to introduce other *N*-aziridines substituents or activating groups.[15] When N-sulfinylaziridine 2-carboxylic acid (+)-**2a** was stirred at 45 °C with 50% aqueous trifluoroacetic acid in acetonitrile for 4 h, aziridine (2*R*,3*S*)-(-)-**7** was isolated in 79% yield (Scheme 4). Alternatively when the reaction was heated at 73 °C for 8 h methyl (2*R*,3*R*)-(+)-α-methyl-β-phenylserine (**8**) was obtained in 75% yield by flash chromatography. In an earlier synthesis of this material, via the reaction of benzaldehyde with a lithiated bis-lactim, Schollkopf et. al reported that the asymmetric induction at C-3 was poor (ca 41%) and that it was a thermally labile oil.[7a,24] By contrast we found methyl (2*R*,3*R*)-(+)-α-methyl-β-phenylserine (**8**) to be a stable, white crystalline solid mp 93-95 °C, ($[\alpha]^{20}_D$ +5.0 (c 0.68, $CHCl_3$)) with IR and NMR consistent with reported values.[25,26]

Scheme 4



In summary, a new methodology is described for the preparation of 2-substituted aziridine 2-carboxylic acids **2** via the highly diastereoselective Darzens-type addition of α-bromo enolates to enantiopure sulfinimines **1**. Regio- and stereocontrolled ring-opening of **2** affords α-methylphenylalanine (**5**) and α-methylphenylserine (**8**) in high enantiomeric purity. The enantiomers of **5** and **8** are similarly available from (*R*)-(-)-**1**. The extension of this methodology to the preparation of other 2-substituted aziridine 2-carboxylic acids is in progress.

Acknowledgments. We thank Mr. George Kemmerer director of NMR facilities at Temple University for help with the NOE experiments. Financial support of this work by the National Institutes of Health is gratefully acknowledged.
