Received October 24, 2004

The synthesis, characterization, and some reactions of the tetrahedral Co₂C₂ cluster-bridged bipyridine (4-C₅H₄NCO₂CH₂)₂C₂Co₂(CO)₆ (**2**) and the diarsine-chelated complexes Pd(dpab)Cl₂ (**3**, dpab = 1,4-bis(diphenylarsino)butane), [Pd(dpab)(H₂O)(OTf)][OTf] (**4**, OTf = SO₃CF₃), Pt(dpab)Cl₂ (**5**), and [Pt(dpab)(H₂O)₂][OTf]₂ (**6**) have been investigated. While the bridged bipyridine **2** could be prepared by reaction of 4-pyridinecarboxylic acid 2-butyne-1,4-diyl ester **1** with Co₂(CO)₈ in 86% yield, the chelated dichloride complexes **3** and **5** were obtained by reaction of K₂PdCl₄ or (PhCN)₂PtCl₂ with dpab in 90% and 77% yields. Further reactions of **3** and **5** with silver triflate followed by treatment with water afforded the corresponding chelated aqua/triflate complexes **4** and **6** in 92% and 88% yields. More interestingly, **4** and **6** were found to undergo self-assembly with **2** to give two cationic metallomacrocycles {[M(dpab)]-μ-[(4-C₅H₄NCO₂CH₂)₂C₂Co₂(CO)₆]}₂[OTf]₄ (**7**, M = Pd; **8**, M = Pt) in 92% and 85% yields. X-ray crystal structures were determined for the Co₂C₂ cluster-containing metallomacrocycles **7** and **8**, as well as bipyridine **2** and complexes **4** and **6**.

Introduction

It is well-known that metallomacrocycles are an important class of metal-containing compounds that have been involved in modern supramolecular chemistry with unique structures and novel properties.^{1–3} On the other hand, it is also known that self-assembly is one of the most practical methodologies for synthesis of metallomacrocycles such as molecular squares,⁴ rectangles,⁵ parallelograms,⁶ and rhomboids,⁷ as well as those metallomacrocycles that contain the redox-active

tetrahedral M₂FeS (M = Mo, W) cluster cores.⁸ Since we are interested in cluster-containing macrocycles,^{8,9} we recently initiated a study on self-assembly of the tetrahedral Co₂C₂ cluster-bridged bipyridine ligand (4-C₅H₄NCO₂CH₂)₂C₂Co₂(CO)₆ (**2**) with the dpab-chelated Pd(II) complex [Pd(dpab)(H₂O)(OTf)][OTf] (**4**, dpab = 1,4-bis(diphenylarsino)butane; OTf = SO₃CF₃) or Pt(II) complex [Pt(dpab)(H₂O)₂][OTf]₂ (**6**), aimed to obtain the corresponding Co₂C₂ cluster-containing metallomacrocyclic compounds that may have unique structures and new properties. Now, we report our results.

Results and Discussion

Synthesis and Characterization of Tetrahedral Co₂C₂ Cluster-Bridged Bipyridine (4-C₅H₄NCO₂CH₂)₂C₂Co₂(CO)₆ (2**).** It was found that treatment of

4-pyridinecarboxylic acid 2-butyne-1,4-diyl ester **1** with $\text{Co}_2(\text{CO})_8$ in petroleum ether at room temperature for 2–3 h resulted in formation of the tetrahedral Co_2C_2 cluster-bridged bipyridine **2** in 86% yield (Scheme 1).

The bridged bipyridine **2** is the first bipyridine derivative containing a cluster core, which was fully characterized by elemental analysis, IR, ^1H NMR, ^{13}C NMR, and X-ray diffraction techniques. For example, the IR spectrum of **2** showed one absorption band at 1728 cm^{-1} for its ester carbonyl groups and four absorption bands in the range $2105\text{--}1993\text{ cm}^{-1}$ for its terminal carbonyls. In addition, the ^1H NMR spectrum of **2** displayed one singlet at 5.55 ppm for its CH_2 groups and two broad singlets at 9.18 and 7.95 ppm for its pyridine rings. The structure of **2** was unequivocally confirmed by X-ray crystallography. The ORTEP drawing of **2** is shown in Figure 1, while Table 1 lists its selected bond lengths and angles. The X-ray crystallography revealed that **2** is indeed a tetrahedral Co_2C_2 cluster-bridged bipyridine in which the $\text{C}(14)\text{--}\text{C}(15)$ bond is essentially perpendicular to the $\text{Co}(1)\text{--}\text{Co}(2)$ bond. In addition, the carbon chain of $\text{C}(13)\text{--}\text{through--}\text{C}(16)$ is attached to $\text{O}(7)$ and $\text{O}(9)$ of the two 4-pyridine carboxylate units, whereas the two cobalt atoms $\text{Co}(1)$ and $\text{Co}(2)$ each are bound to three terminal carbonyls. The $\text{Co}(1)\text{--}\text{Co}(2)$ ($2.4817(9)\text{ \AA}$) and $\text{C}(14)\text{--}\text{C}(15)$ ($1.343(3)\text{ \AA}$) distances as well as the $\text{C}(13)\text{--}\text{C}(14)\text{--}\text{C}(15)$ ($139.6(2)^\circ$) and $\text{C}(14)\text{--}\text{C}(15)\text{--}\text{C}(16)$ ($141.2(2)^\circ$) angles are all comparable with those found for other tetrahedral Co_2C_2 systems.¹⁰ More interestingly, this complex has been proved to be a very efficient ligand for self-assembly of the desired cluster-containing macrocycles (vide infra).

Synthesis and Characterization of dpab-Chelated Pd(II) Complexes $\text{Pd}(\text{dpab})\text{Cl}_2$ (3**) and $[\text{Pd}(\text{dpab})(\text{H}_2\text{O})(\text{OTf})][\text{OTf}]$ (**4**).** We further found that reaction of K_2PdCl_4 with dpab in EtOH at room temperature for 12 h gave the Pd(II) dichloride complex **3** in 90% yield, whereas complex **3** reacted with silver triflate in CH_2Cl_2 at room temperature for 24 h followed by 10 min stirring in air to afford the Pd(II) monoaqua complex **4** in 93% yield (Scheme 2).

It is worth pointing out that the starting material dpab ligand was prepared by a new route. This route

Figure 1. Molecular structure of **2** (thermal ellipsoids with 30% probability).

Scheme 2

involves reaction of 1,4-dibromobutane with lithium followed by treatment of the intermediate $\text{Li}(\text{CH}_2)_4\text{Li}$ with Ph_2AsCl . This route has much higher yield (73% vs 15%) than that previously reported involving reaction of Ph_3As with potassium and subsequent treatment of the intermediate Ph_2AsK with 1,4-dichlorobutane.¹¹ In addition, it is believed^{4a,b} that reaction of complex **3** with silver triflate might first give bis(triflate) complex $\text{Pd}(\text{dpab})(\text{OTf})_2$, and the monoaqua complex **4** was produced by hydrolysis of $\text{Pd}(\text{dpab})(\text{OTf})_2$ in the workup process with 10 min stirring in open air.

Complexes **3** and **4** are new and have been characterized by elemental analysis and spectroscopy. For example, the ^1H NMR spectrum of **3** displayed two singlets at 2.68 and 1.68 ppm for its $\alpha\text{-CH}_2$ and $\beta\text{-CH}_2$ groups in the dpab ligand, whereas the spectrum of **4** showed two singlets at 2.55 and 2.16 ppm for its $\alpha\text{-CH}_2$ and $\beta\text{-CH}_2$ groups in the dpab ligand. The ^{19}F NMR spectrum of **4** showed only one singlet at -78.80 ppm , although it has one coordinated OTf and one uncoordinated OTf group (see its crystal structure below). In addition, the ^1H NMR and IR spectra of **4** indicated the presence of H_2O by showing a broad singlet at 4.63 ppm and a broad absorption band at 3201 cm^{-1} , respectively.

The molecular structure of **4** was unambiguously established by crystal X-ray diffraction techniques. While Figure 2 shows its ORTEP drawing, Table 2 lists selected bond lengths and angles. X-ray diffraction confirmed that this molecule contains one $[\text{OTf}]^-$ anion and one $[\text{Pd}(\text{dpab})(\text{H}_2\text{O})(\text{OTf})]^+$ cation. So, it is the first Pd(II) complex that contains one molecule of H_2O and one OTf as ligands, although numerous Pd(II) complexes usually contain either two molecules of H_2O or two OTf ligands.^{4a,b} The $\text{Pd}(1)\text{--}\text{As}(1)$ distance ($2.3540(10)\text{ \AA}$) is slightly longer than the $\text{Pd}(1)\text{--}\text{As}(2)$ distance ($2.3310(9)\text{ \AA}$), whereas the $\text{Pd}(1)\text{--}\text{O}(1)$ distance ($2.145(3)\text{ \AA}$) is

slightly longer than the Pd(1)–O(4) distance (2.121(3) Å). The sum of bond angles O(4)–Pd(1)–O(1), O(4)–Pd(1)–As(2), O(1)–Pd(1)–As(1), and As(2)–Pd(1)–As(1) is exactly 360°, implying that Pd(1) adopts a square-planar coordination geometry. Figure 2 also shows that there are two types of intramolecular hydrogen bonding¹² in the solid state of complex **4**. The first one is the O(4)–H(1)···O(3) hydrogen bond, which is formed between the coordinated H₂O and the coordinated OTf, whose bond length and bond angle are 2.755 Å and 175.01°. Another one is O(4)–H(2)···O(7), which is formed between the coordinated H₂O and the uncoordinated OTf, whose bond length and bond angle are 2.702 Å and 169.36°, respectively. Obviously, the higher air and thermal stability of complex **4** compared to the intermediate bis(triflate) complex is due to the presence of such hydrogen bonding in monoaqua complex **4**. In fact, the role of hydrogen bonding in the stabilization of the solid-state structure of aqua-transition metal complexes has long been recognized.¹³

Synthesis and Characterization of dpab-Chelated Pt(II) Complexes Pt(dpab)Cl₂ (5**) and [Pt(dpab)(H₂O)₂][OTf]₂ (**6**).** Similar to the preparation

Scheme 3

of complexes **3** and **4**, we also found that reaction of (PhCN)₂PtCl₂ with dpab in toluene at room temperature for 24 h afforded the Pt(II) dichloride complex **5** in 77% yield, whereas the Pt(II) diaqua complex **6** could be prepared by reaction of complex **5** with silver triflate in CH₂Cl₂ at room temperature followed by 10 min stirring in air (Scheme 3).

Although diphosphine-chelated Pt(II) complexes with a general formula of diphosphine PtX₂ (X = Cl, H₂O, OTf)^{4a,b} are known, **5** and **6** are the first such diarsine-chelated Pt(II) complexes prepared so far. Complexes **5** and **6** are air-stable solids and have been characterized by elemental analysis and spectroscopy. The ¹H NMR spectrum of **5** showed two singlets at 2.69 and 1.69 ppm for its α-CH₂ and β-CH₂ groups in the dpab ligand, while the spectrum of **6** displayed two singlets at 2.74 and 1.87 ppm for its α-CH₂ and β-CH₂ groups in the dpab ligand. In addition, the IR spectrum of **6** displayed a broad band at 3054 cm⁻¹, indicating the presence of water. The ¹⁹F NMR spectrum of **6** exhibited one singlet at -77.96 ppm for its two uncoordinated OTf groups. This singlet is just slightly shifted downfield compared to that caused by the two uncoordinated OTf groups in the diphosphine-chelated complex [Pt(dppf)(H₂O)₂][OTf]₂.^{4b}

The structure of complex **6** was confirmed by crystal X-ray diffraction analysis. The ORTEP diagram of **6** is presented in Figure 3, whereas selected bond lengths and angles are listed in Table 3. As can be seen in Figure 3, the transition metal Pt(1) is attached to two

Figure 3. Molecular structure of **6** (thermal ellipsoids with 30% probability).

Scheme 4

molecules of water through O(1) and O(2) and one molecule of dpab through As(1) and As(2). The Pt–As bond lengths are 2.3311(9) and 2.3272(10) Å, whereas the Pt–O bond lengths are 2.115(6) and 2.126(6) Å, respectively. The bond angle around Pt(1) is exactly 360°, which means that the geometry of Pt(1) is square-planar. This molecule contains two uncoordinated counteranions [OTf][−], which interact with the cation [Pt(dpab)(H₂O)₂]⁺ through four identical intramolecular hydrogen bonds¹² formed between the two coordinated H₂O and the two uncoordinated OTf groups (Figure 3). The bond lengths of these hydrogen bonds are O(1)–H(101)···O(3) = 2.620 Å, O(1)–H(201)···O(7) = 2.656 Å, O(2)–H(102)···O(5) = 2.683 Å, and O(2)–H(202)···O(8) = 2.676 Å, whereas the bond angles of these hydrogen bonds are equal to 145.1°, 147.7°, 150.4°, and 151.5°, respectively. Similar to the mono-aqua complex 4, diaqua complex 6, due to having such hydrogen bonding, is much more stable than its bis(triflate) complex.¹³

Synthesis and Characterization of Metal Cluster-Containing Macrocycles {[M(dpab)]-μ-[(4-C₅H₄-NCO₂CH₂)₂C₂Co₂(CO)₆]}₂[OTf]₄ (**7**, *M* = Pd; **8**, *M* = Pt). More interestingly, we found that the tetrahedral Co₂C₂ cluster-bridged bipyridine ligand **2** could undergo self-assembly reaction with mono-aqua Pd(II) complex **4** or diaqua Pt(II) complex **6** in dichloromethane at room temperature to give the corresponding tetrahedral cluster-containing metallomacrocycles **7** and **8** in 93% and 85% yields, respectively (Scheme 4).

Complexes **7** and **8** are air-stable solids, which have been fully characterized by elemental analysis, spectroscopy, and X-ray diffraction study. The IR spectra of **7** and **8** showed three strong absorption bands in the range 2100–2032 cm^{−1} for their terminal carbonyls and

one strong absorption band at 1738 cm^{−1} for their ester carbonyls. The presence of triflate counterions in **7** and **8** is indicated by one singlet in their ¹⁹F NMR spectra at −78.26 and −77.11 ppm, respectively. Thus, the ¹⁹F NMR behavior of the triflates in **7** and **8** is very close to that of the triflates in their precursors **4** and **6** and even those of the diphosphine-chelated Pd(II) and Pt(II) complexes.^{4a,b}

Figures 4 and 5 show the ORTEP diagrams of the cationic parts of **7** and **8**, while selected bond lengths and angles are given in Tables 4 and 5, respectively. In fact, **7** and **8** are isostructural, and their macrocyclic

cations each contain two dpab-chelated transition metal Pd or Pt moieties that are held together by two molecules of the tetrahedral Co₂C₂ cluster-bridged bipyridine ligands. The coordination geometry around Pd(1)/Pd(1A) or Pt(1)/Pt(1A) metal centers is normal square-planar with slight deviations of the bond angles. All Pd–As or Pt–As distances are normal within the range 2.374–2.387 or 2.373–2.375 Å, respectively. Likewise, the Pd–N and Pt–N distances are normal with the region 2.070–2.092 Å or 2.126–2.138 Å, whereas the N–Pd–N and N–Pt–N angles are 87.0(4)° or 87.5(3)°, respectively. In fact, the geometric parameters of **7** and **8** are comparable with those for other Pd(II) and Pt(II) macrocycles containing bidentate N ligands.^{4a,7} The additional important geometric features for **7** and **8** are that (i) both molecules are centrosymmetric, (ii) the two pyridine rings in each bipyridine ligand **2** of **7** or **8** are cis to the Co₂(CO)₆ moiety of the tetrahedral Co₂C₂ cluster unit, (iii) the four pyridine rings and the Co(1)–Co(2)–Co(1A)–Co(2A) plane in **7** and **8** are nearly perpendicular to the plane defined by the six atoms Pd(1), C(36), C(37), Pd(1A), C(36A), and C(37A) in **7** or the six atoms Pt(1), C(14), C(15), Pt(1A), C(14A), and C(15A) in **8** respectively, and (iv) the two Pd or two Pt atoms and the four Co atoms in **7** and **8** are located at six apical positions of an octahedron. It follows that the structures of **7** and **8**, in contrast to those metallomacrocycles without cluster-bridged N donor ligands,^{4–7} are unique and unprecedented.

Conclusions

We have first synthesized and characterized the tetrahedral Co₂C₂ cluster-bridged bipyridine ligand **2** and the diarsine dpab-chelated Pd(II)/Pt(II) complexes **3**–**6**. Study on self-assembly of ligand **2** with complex **4** or **6** has allowed us to obtain two metallomacrocyclic compounds **7** and **8**, which contain the corresponding

Co₂C₂ cluster cores and represent a unique and interesting class of metallomacrocycles. Further studies on the possible new properties caused by the Co₂C₂ cluster cores^{10a} in **7** and **8** and the self-assembly reactions of either bipyridine ligand **2** with other metal complexes or complexes **4** and **6** with other cluster-bridged bipyridine ligands are in progress in this laboratory.

Experimental Section

General Comments. All reactions were carried out under highly purified nitrogen atmosphere using standard Schlenk or vacuum-line techniques. Solvents for preparative use were dried and distilled under nitrogen from CaH₂ or sodium/benzophenone ketyl prior to use. All solvents were bubbled for at least 15 min before use. 1,4-Dibromobutane, K₂PdCl₄, silver triflate, and Co₂(CO)₈ were of commercial origin and used as received. 4-Pyridinecarboxylic acid 2-butyne-1,4-diyl ester,¹⁴ Ph₂AsCl,¹⁵ and (PhCN)₂PtCl₂¹⁶ were prepared according to literature methods. ¹H NMR spectra were recorded on a Bruker AC-P 200 or a Bruker 300M NMR spectrometer, and chemical shifts are reported in ppm relative to internal Me₄Si (δ = 0). ¹⁹F NMR spectra were measured on a Bruker 300M spectrometer, and chemical shifts are referenced relative to external CF₃CO₂D (δ = 0). IR spectra were taken on a Bio-Rad FTS 135 spectrophotometer. Elemental analysis was performed on an Elementar Vario EL analyzer, and melting points were determined on a Yanaco MP-500 melting point apparatus.

Improved Preparation of Ph₂As(CH₂)₄AsPh₂ (dpab).¹¹

A Schlenk flask was charged with 0.1 g (14.4 mmol) of lithium and 20 mL of diethyl ether. Under stirring, the mixture was cooled to -40 °C and then a solution of 0.41 mL (3.5 mmol) of 1,4-dibromobutane in 20 mL of diethyl ether was slowly added.

After the new mixture was warmed to room temperature and stirred for 18 h, it was filtered to give a filtrate containing 1,4-dilithiumbutane.¹⁷ The filtrate was cooled to −20 °C, and then 1 mL (5.57 mmol) of Ph₂AsCl was added. The new mixture was warmed to room temperature and stirred at this temperature for 12 h. To this mixture was added 10 mL of water, and the resulting mixture was stirred for an additional 0.5 h. The organic layer was separated, washed twice with water, and dried over anhydrous MgSO₄. After removal of MgSO₄ and solvent, the residue was recrystallized from diethyl ether to give 1.32 g (73%) of dpab as a white solid.

Preparation of (4-C₅H₄NCO₂CH₂)₂C₂Co₂(CO)₆ (2**).** A Schlenk flask was charged with 0.445 g (1.5 mmol) of 4-pyridinecarboxylic acid 2-butyne-1,4-diyl ester and 30 mL of petroleum ether. While stirring, a solution of 0.514 g (1.5 mmol) of Co₂(CO)₈ in 15 mL of petroleum ether was slowly added. The mixture was stirred at room temperature for an additional 2–3 h until no CO evolution was observed. Solvent was removed under reduced pressure, and the residue was subjected to column chromatography (alkali Al₂O₃) using CHCl₃ as eluent. The crude product obtained from the eluted red band was recrystallized from CH₂Cl₂/petroleum ether to give 0.747 g (86%) of **2** as a red solid. Mp: 130 °C dec. Anal. X-ray Structure Determinations of 2, 4, 6, 7, and 8. X-ray quality single crystals of **2** were grown by slow evaporation of its dichloromethane/petroleum ether solution at 4 °C, whereas those of **4** and **6** were obtained by slow diffusion of diethyl ether or hexane into their dichloromethane solutions

at room temperature, respectively. While the single crystals of **7** were grown by slow diffusion of diethyl ether into its nitromethane solution containing several drops of glacial acetic acid at room temperature, those of **8** were produced by slow diffusion reaction of an acetone solution of ligand **2** into a dichloromethane solution of complex **6** under nitrogen at room temperature. However, since the single crystals of **8** are highly efflorescent even under nitrogen, they must be sealed with great care in a capillary immediately after being taken out from the crystal-growing solvent system. Each crystal suitable for X-ray diffraction analysis was mounted on a Bruker SMART 1000 automated diffractometer. Data were collected at 293(2) K using Mo K α graphite-monochromated radiation (λ = 0.71073 Å) in the ω scanning mode. Absorption corrections were performed using SADABS. The structures were solved by direct methods using the SHELXTL-97 program. The final refinements were accomplished by the full-matrix least-squares method with anisotropic thermal parameters for non-hydrogen atoms. All hydrogen atoms were located by using the geometric method. Details of the crystal data, data collections, and structure refinements are summarized in Tables 5 and 6, respectively.

Acknowledgment. We are grateful to the National Natural Science Foundation of China and the Research Fund for the Doctoral Program of Higher Education of China for financial support.
