

$I > 3\sigma(I)$ were used in the full-matrix least-squares refinement after analytical absorption correction. Non-hydrogen atoms were refined in (x, y, z, U_{ij}) and hydrogen atoms in (x, y, z, U) . At convergence R, R' were 0.039 and 0.047, reflection weights being $(\sigma^2(F_o) + 0.0005(F_o)^2)^{-1}$. Neutral atom scattering factors were used, those for the non-hydrogen atoms being corrected for anomalous dispersion ($f''f''$).²² Computation was carried out by using the X-RAY 76 program system²³ implemented by S. R. Hall on a Perkin-Elmer 3240 computer.

Department of Chemistry, University of Montreal
Montreal, Québec, Canada H3C 3V1

Received May 11, 1982

Among the landmark achievements in natural product synthesis in 1980 was Kishi's conquest of the rifamycin S structure.² In considering synthetic approaches³ to this formidable target,⁴ one is faced with several challenging problems, not the least of which is the construction of the sequence of alternating methyl and hydroxyl groups situated in the C19–C29 aliphatic segment and encompassing eight contiguous asymmetric centers. We report on the assembly of the aliphatic segment of rifamycin S based on a strategy that recognizes *hidden carbohydrate-type symmetry*⁵ as illustrated in Scheme I. Bond disconnection at C24–C25 generates two segments representing C19–C24 and C25–C29, which can be related to two "chiral templates" derived from D-glucose and designated as precursors A and B.

Precursor A. The synthesis of precursor A as shown in Scheme II starts with the readily available and crystalline epoxide **1**,⁶ which

^a Key: (a) Ethyldimethylaminopropyl carbodiimide, HCl, Me₂SO, quantitative; (b) NaOMe, MeOH, 85%; (c) NaBH₄, MeOH, 97%; (d) SO₂Cl₂, pyridine -75 to 25 °C, 18 h, 75%; (e) *n*-Bu₃SnH, AIBN, toluene, reflux, quantitative; (f) 50% aqueous AcOH, 80 °C, 2.5 h, then NaBH₄, EtOH, 80%; (g) 2,2-dimethoxypropane, TsOH·H₂O, THF, 78%; (h) pyridinium chlorochromate, 4-Å sieves, CH₂Cl₂, 5 min, 72%.

C-methyl substituent corresponding to C22 was achieved via a stereoselective hydroxyl-assisted catalytic hydrogenation of the allylic alcohol derivative 3, [α]_D +104.3°, which was readily available from 2. The resulting epimeric mixture (4:1 axial/equatorial) was benzylated and separated by chromatography to give the desired intermediate 5, [α]_D +25.6° (¹H NMR δ 0.94 (C-2 Me), 0.79 (C-4 Me), and the latter was homologated to 7, [α]_D +37° (¹H NMR δ 4.44 (d, *J* = 4.4 Hz, (H-1), 0.94 (C-2 Me), 0.86 (C-4 Me)) in good overall yield. Having thus taken advantage of the inherent conformational and topological properties of cyclic carbohydrate-derived intermediates in securing the three asymmetric carbon atoms corresponding to C20–C22, we were ready to consider various transforms into acyclic structures representing the six-carbon framework spanning C19–C24 of the target.⁹ In one such option, 7 was transformed into the acyclic ketone 8, mp 91–92 °C, [α]_D -8.9°, whose synthetic utility as a carbanionic equivalent of the C19–C24 segment of rifamycin S can be clearly appreciated.

Precursor B. Intermediate 2 used in the previous sequence was the starting point for the elaboration of precursor B, in which we intended to incorporate the asymmetric centers corresponding to C26 and C27 (Scheme III). Thus, manipulation of 2 by a three-step high-yielding sequence involving crystalline intermediates⁷ afforded the known crystalline derivative 9. Convergence with the desired template (precursor B) required inversion at C3 and deoxygenation at C4. The first operation was achieved by an oxidation–epimerization process⁷ which led to the crystalline ketone 10, mp 137.5–138.5 °C, [α]_D +130.1°, and the second was achieved by reduction of 10 to the alcohol, chlorination,¹⁰ and tributyltin hydride mediated reductive dechlorination¹¹ to give 11, [α]_D +76.1°. Once again, the cyclic templates having served their purpose, it was time to exploit their utility as acyclic derivatives. A two-step sequence provided the triol 12, which presented unique opportunities for functionalization at the C1 position (C25 in rifamycin S).¹² Of the several options available, it was decided to utilize the extended C25–C29 segment as an electrophilic partner represented by aldehyde 13 (¹H NMR δ 9.81 (CHO), 3.47 OMe), 1.11 (C-2 Me), etc.; Scheme III).

Depolymerized with a number of useful intermediates, we were now in a position to address the question of assembling the acyclic carbon backbone of our target by one of several carbon–carbon bond-forming reactions as per our original synthetic blueprint. One

Scheme IV^a

^a Key: (a) 8 in THF, -78 °C, LDA, 30 min, add 13, -70 °C, 10 min, 76%; (b) Dibal, toluene, -78 °C, 2 h, then 25 °C; (c) 10% Pd/C, H₂, MeOH, separate major isomer, 73%; (d) 70% aqueous AcOH, 45 °C, 90 min, ~quantitative; (e) aqueous NaIO₄, MeOH, 10 min, then NaBH₄; (f) 2,2-dimethoxypropane, CSA, 36 h, 60%; (g) Ac₂O, EtOAc, DMAP, 50 °C, 3 h, 80%.

attractive option called for engaging intermediates 8 and 13 in a cross-aldol reaction via a metal enolate.^{13,14} We reasoned that by virtue of the presence of a β -alkoxy substituent in the ketone component, it could be possible to generate metal-coordinated

(9) Other derivatives incorporating epoxide (C23–C24), aldehyde (C23), and phenyl sulfoxide (C24) functions were prepared and their electrophilic and nucleophilic reactivities studied.

(10) See for example: Jennings, H. J.; Jones, J. K. N. *Can. J. Chem.* **1965**, *43*, 2372–2386. Hanessian, S.; Vatele, J.-M., *Tetrahedron Lett.* **1981**, 22, 3579–3582.

species from the prerequisite *Z* enolate such that we could bias the stereoselection in favor of the syn (erythro) diastereoisomers and, perhaps more specifically, the 2*S*,25*R* component.^{15,16} A cross-aldol reaction between the lithium enolate derived from **8** and the aldehyde **13** was effected under time and temperature controlled conditions to afford a mixture of two diastereomeric products **14**, $[\alpha]_D -17.16^\circ$, in 76% yield (Scheme IV), in which the desired 2*S*,25*R* syn isomer was a major component (>7:3).

At this juncture, it was therefore of paramount importance to secure an appropriate degradation product of rifamycin S that contained the intact C19–C29 segment and to be able to establish the constitutional and configurational identity of the aldol product **14**. Degradation of rifamycin S is known to provide a dienic ester fragment **20**.¹⁷ This was further manipulated¹⁸ to give the acetal **17**, mp 73–74 °C, $[\alpha]_D +20^\circ$, and the pentaacetate derivative **19**, $[\alpha]_D \sim 0^\circ$,¹⁹ which were suitable compounds for our correlation. Reduction of the C23 carbonyl function with diisobutylaluminum hydride proceeded with high stereoselectivity (>10:1) to give the desired **15**. Catalytic hydrogenolysis produced major compound **16**,²⁰ $[\alpha]_D -3.2^\circ$, which was further transformed into the crystalline

hemiacetal and syrupy pentaacetate derivatives **17** and **19**, respectively, and found to be identical in all respects with samples obtained from **20** (TLC, $[\alpha]_D$, 400 MHz and two-dimensional ¹H NMR, mass spectroscopy).

Since intermediates such as **16** and **18** can be easily converted to one of Kishi's advanced intermediates, our approach as reported herein represents a formal synthesis of the optically active antibiotic.^{21,22}
