The stereochemistry of alcohols 21 and 22 was established by the following experiments. Benzylation of the major alcohol 22 followed by aqueous acid hydrolysis, periodate oxidation, and sodium borohydride reduction afforded 2-(benzyloxy)hex-5-en-1-ol (23). The α_D value of 23 was found to be -9.4°. The specific

24

rotations of (R)- and (S)-2-(benzyloxy)hex-5-en-1-ols, prepared from D- and L-glyceraldehyde ketals, 23 were found to be -11.7and +10.4°, respectively. Thus, C88 has the S configuration in the minor alcohol 21. This conclusion was further confirmed by comparison of the ¹H NMR spectra of MTPA²⁵ esters of 23 obtained from the above-mentioned sources.

The experiments summarized above allowed us to assign the stereochemistry of degradation product 10 as indicated. Since this assignment of the relative stereochemistry between C90 and C91 was based solely on the results of Sharpless' asymmetric epoxidation⁸ of 15, we felt it was desirable to have additional evidence.²⁶ For this reason, the stereochemistry assignment at C88, C89, and C90 was performed by an alternative method. Thus, cis-allylic alcohols 24 were prepared from 14²⁴ and subjected to OsO4 oxidation, aqueous acid hydrolysis, debenzylation, and acetylation to yield a mixture of nonaacetates corresponding to 10. However, none of these nonaacetates was identical with degradation product 10, establishing the relative stereochemistry at C88 and C89 as threo. This information, along with knowledge of the relative stereochemistry between C89 and C90 and of the absolute stereochemistry at C88 and C91 (vide supra), excluded all possible structures for degradation product 10 except the one

Continuing from the preceding communication, we will describe the stereochemistry assignment of the C1-C6, C47-C74, and C77-C83 portions of the marine natural product palytoxin.²

The lactone diacetate 1 (Chart I), containing C1-C6, is a known degradation product of palytoxin. The ¹H NMR spectrum of 1 suggested that the relative stereochemistry at C2, C3, and C5 was as indicated in 1, but the absolute stereochemistry was unknown.³ By use of the carbohydrate chain-extension method,⁴ tetraacetate **2**⁵ [¹H NMR (CDCl₃) δ 0.97 (3 H, d, J = 6.9 Hz), 2.05 (3 H, s), 2.06 (3 H, s), 2.07 (3 H, s), 2.09 (3 H, s); $\alpha_D + 17.0^{\circ}$ (c 0.17, CHCl₃)] was synthesized from (S)-(+)-3-hydroxy-2-methylpropionic acid.^{6,7} Upon comparison of spectroscopic data and optical rotations, tetraacetate 2 was found to be identical with the tetraacetate prepared from the degradation product,8 establishing the absolute stereochemistry of C2, C3, and C5.

The tetraacetate 3, containing C47-C56, was isolated as a degradation product of palytoxin. By use of the carbohydrate chain-extension method, triacetate 4 [¹H NMR (CDCl₃) δ 0.95 (3 H, d, J = 7.4 Hz), 2.02 (3 H, s), 2.03 (3 H, s), 2.04 (3 H, s); α_D -14.2° (c 0.73, CH₂Cl₂)] and its C49 diastereomer were synthesized from (S)-(+)-3-hydroxy-2-methylpropionic acid.^{6,7} On comparison of spectroscopic data and optical rotations, triacetate 4 was found to be identical with advanced degradation product 4.10 Wittig reaction of aldehyde 67 with phosphonium salt 57 followed by debenzylation and acetylation gave trans-olefin 3 [1 H NMR (CDCl₃) δ 1.01 (3 H, d, J = 7.0 Hz), 2.03 (3 H, s), 2.04 (3 H, s), 2.05 (6 H, s)]. Starting with 5 and the antipode⁷ of 6, the C53 diastereomer of 3 was also prepared. Upon comparison of ¹H NMR data, synthetic tetraacetate 3 was found to be identical with degradation product 3, establishing the stereochemistry at C49, C50, and C53.

The pentaacetate 7, which contains C77-C83, is a degradation product of palytoxin. The relative stereochemistry of 7 was found

⁽²³⁾ D-Glyceraldehyde acetonide was prepared according to the method reported in the following: Fischer, H. O. L.; Baer, E. Helv. Chim. Acta 1934, 17, 622). With the procedure reported for the D-series (Zinner, H.; Milbradt, J. Carbohydr. Res. 1966, 2, 470), L-glyceraldehyde cyclohexanone ketal was prepared from L-arabinose. Transformation of glyceraldehyde ketals into 23 was achieved in eight steps.²⁴

⁽²⁴⁾ Details of this synthesis are given in the supplementary material. (25) Dale, J. A.; Dull, D. L.; Mosher, H. S. J. Org. Chem. 1969, 34, 2543. Sullivan, G. R.; Dale, J. A.; Mosher, H. S. Ibid. 1973, 38, 2143

⁽²⁶⁾ Chemical correlation of optically active epoxides prepared by asymmetric epoxidation has been performed in many cases; for example, see footnotes 6, 8, and 9.

[†]This work was presented by Y. Kishi as part of a lecture at the symposium honoring the memory of Dr. Willy Leimgruber on March 26, 1982, at Rutgers University, Newark, NJ.

⁽¹⁾ Part 1 of this series: J. Am. Chem. Soc. preceding paper in this issue. (2) For the structure and numbering of palytoxin, see part 4 of this series.

⁽³⁾ This assignment was made based on the spin-spin coupling constants $J_{2,3} = 11.6$ Hz and $J_{4,5} = 12.0$ and 3.5 Hz, given in the supplementary material for ref la of the preceding paper.

⁽⁴⁾ See ref 6 in the preceding paper.

⁽⁵⁾ Satisfactory spectroscopic data were obtained for all new compounds

in this paper.

(6) We are indebted to Dr. Cohen, Hoffmann-La Roche Inc., for a generous gift of this acid.

⁽⁷⁾ Details of this synthesis are given in the supplementary material. (8) This substance was prepared from the degradation product reported as compound 1 in ref 2f of the preceding paper in four steps: (1) $O_3/$ MeOH/-78 °C, followed by NaBH₄ workup; (2) Ac₂O/py; (3) LiAlH₄/THF/0 °C; (4) Ac₂O/py.
(9) See ref 2f and 2d in the preceding paper.

⁽¹⁰⁾ This substance was prepared from the degradation product reported as compound 21 in ref 1a of the preceding paper in three steps: (1) NaOH/MeOH/room temperature; (2) NaIO₄/H₂O/0 °C, followed by NaBH₄ workup: (3) Ac₂O/py, followed by TLC separation.

by NMR experiments to be as indicated, but the absolute stereochemistry remained unknown.11 Synthesis of pentaacetate 7 from 2-deoxy-D-glucose via nitrile 8 was performed straightforwardly. Upon comparison of α_D values, synthetic pentaacetate 7 [${}^{1}\text{H-NMR}$ (CDCl₃) δ 2.04 (6 H, s), 2.05 (3 H, s), 2.06 (3 H, s), 2.15 (3 H, s); α_D +53.4° (c 0.46, CHCl₃)] was found to be identical with degradation product 7 (Chart II). To determine the connectivity of 7 with the remaining portions of the palytoxin structure, we performed a stepwise degradation reaction. Palytoxin was partially degraded to 9,11 which was then ozonized and treated with acetic anhydride/pyridine to yield trans- α,β -unsaturated aldehyde 10. Synthesis of the two possible diastereomers, i.e., **10** [${}^{1}H$ NMR (CDCl₃) δ 2.05 (3 H, s), 2.07 (3 H, s), 2.18 (3 H, s), 6.22 (1 H, ddd, J = 16, 7.6, 1.5 Hz), 6.72 (1 H, dd, J = 16, 4.6), 9.57 (1 H, d, J = 7.6)] and its C80 diastereomer, was achieved from 8.7 Upon comparison of the ¹H NMR spectra, synthetic 10 was found to be identical with degradation product 10, establishing the stereochemistry of C79, C80, and C81 as

We then turned our attention to degradation product 11 (Chart III), containing the C52–C74 carbon backbone of palytoxin. The H NMR spectrum of 11 provided valuable information on the relative stereochemistry of the cyclic portions, indicating it to be as shown in 11. In addition, two more advanced degradation

Chart III

11

Chart IV

$$\underline{14}: R = \bigcirc$$

products 1213 and 1314 were useful in this study.

The synthesis of 16 (the antipode of 13) was next accomplished. The trans-allylic alcohol 14 (Chart IV), synthesized from D-glucose, was subjected to Sharpless' asymmetric epoxidation by using L(+)-diethyl tartrate to yield the expected epoxide 15. Regioselective reductive epoxide opening of 15⁴ followed by acetylation, debenzylation, periodate oxidation, borohydride reduction, and acetylation furnished pentaacetate 16 [1 H NMR C₆D₆) δ 1.72 (3 H, s), 1.74 (3 H, s), 1.76 (3 H, s), 1.81 (3 H, s), 1.83 (3 H, s); α_D +9.8° (c 0.05, CHCl₃)]. The C73 epimer of 16 was also synthesized from 14 by treatment with the same sequence of reagents except for D(-)-diethyl tartrate in the asymmetric epoxidation. Upon comparison of spectroscopic data and optical rotations, 16 was found to be the antipode of degradation product 13 [α_D -8.9° (c 0.09, CHCl₃)], establishing the stereochemistry at C67, C71, and C73. The stereochemistry C68, C69, and C70 was not determined directly by this synthesis but

⁽¹¹⁾ See ref 2b and 1a in the preceding paper.

⁽¹²⁾ This was concluded based on the values of $J_{60,61}$, $J_{61,62}$, $J_{67,68}$, $J_{68,69}$, and $J_{70,71}$ reported for 11: see ref 2b, 2a, and 1a in the preceding paper.

⁽¹³⁾ See ref 2b and 2a in the preceding paper.

⁽¹⁴⁾ This substance was prepared from the degradation product reported as compound 12 in ref 2b of the preceding paper in two steps: (1) $O_3/MeOH/-78$ °C, followed by NaBH₄ workup; (2) Ac_2O/py .

⁽¹⁵⁾ See ref 8 in the preceding paper.

$$\frac{2$$

was concluded with reasonable confidence from the aforementioned ¹H NMR data and was later confirmed by synthesis (vide infra).

The stereochemistry of degradation product 12 was established by the following synthesis. Trans-allylic alcohol 17, prepared from 2-deoxy-D-glucose, was subjected to asymmetric epoxidation 15 using D(-)-diethyl tartrate to yield the expected epoxide 18 as the major product. Camphorsulfonic acid treatment of 18 in acetone at room temperature gave acetonide 19 (Chart V) as the sole product. Grignard reaction of aldehyde 20, prepared from 19,7 with 3-butenylmagnesium bromide in ether gave a 6:1 mixture of alcohols 21 and 22.16 Upon comparison of spectroscopic data and optical rotations, hexaacetate 12 [^{1}H NMR ($C_{6}D_{6}$) δ 1.71 $(3 \text{ H, s}), 1.79 (12 \text{ H, s}), 1.81 (3 \text{ H, s}); \alpha_D + 7.8^{\circ} (c \ 0.16, \text{CHCl}_3)],$ obtained from the minor alcohol 22,7 was found to be identical with degradation product 12 while the corresponding hexaacetate derived from the major alcohol 21 was different, establishing the stereochemistry at C57, C58, and C62. The relative stereochemistry between C56 and C57, which was not confirmed by this synthesis, was found to be erythro as follows. Wittig reaction of aldehyde 237 with phosphonium salt 247 yielded cis-olefin 25 $(J_{56.57} = 11.0 \text{ Hz})$. After modification of the R² side chain, 25 was subjected to osmium tetroxide oxidation to furnish a 7:1 mixture of the two possible erythro diols. Upon comparison of spectroscopic data, hexaacetate 12 derived from the major erythro diol7 was found to be identical with degradation product 12.

The relative stereochemistry between C64 and C65 was determined as follows. Wittig reaction of phosphonium salt 28, prepared from 27,7 with aldehyde 29, prepared from 26,7 gave cis-olefin 30 (Chart VI). The stereochemistry of the olefinic bond was established by the spin-spin coupling constant $(J_{64,65} = 11.4 \text{ Hz})$ of the olefinic protons. Osmium tetroxide oxidation of 30

Chart VI

followed by acetylation, aqueous acid hydrolysis, debenzylation, and acetylation yielded a 1:1 mixture of two erythro acetates. Neither was found to be identical with degradation product 11 upon comparison of spectroscopic data. Photochemically induced double-bond isomerization of 30 gave a mixture of trans-olefin 31 ($J_{64,65} = 15.5 \text{ Hz}$) and cis-olefin 30. Osmium tetroxide oxidation of 31 followed by conversion to the polyacetates as before yielded a 2:1 mixture of threo-acetate 11 [¹H NMR (C_6D_6) δ 1.68 (3 H, s), 1.70 (3 H, s), 1.75 (6 H, s), 1.78 (3 H, s), 1.79 (3 H, s), 1.80 (3 H, s), 1.81 (3 H, s), 1.84 (3 H, s), 1.86 (3 H, s), 1.88 (3 H, s), 1.93 (3 H, s), 2.02 (3 H, s); α_D +18.4° (c 0.69, CHCl₃)] and its C64–C65 diastereomer. Upon comparison of spectroscopic data and optical rotations, one of the threo isomers was found to be identical with degradation product 11.

The absolute configuration at C65 was established as follows. Wittig reaction of phosphonium salt 32, prepared from 26,7 with aldehyde 33, prepared from 27,7 produced a cis olefin, which was sequentially subjected to hydroboration, aqueous acid hydrolysis, debenzylation, and acetylation to yield a mixture of acetates. Upon comparison of spectroscopic data, one of these acetates was found to be identical with degradation product 11. Assignment of the absolute configurations at C65 and C73 was based on Sharpless' asymmetric epoxidation¹⁵ used in the course of the synthesis of 33. This assignment was further supported by the fact that the heptaacetate prepared from 3317 was a meso compound—note the symmetry of this substance. Since the relative stereochemistry between C64 and C65 was shown to be threo (vide supra), the absolute stereochemistry of C64 was now known. Thus, the stereochemistry of the degradation product 11 is as shown in the structure.

(18) Note Added in Proof: The absolute configuration at C64 and C65 was further confirmed as follows. Hexa-1,3,4,6-tetraol 3,4-acetonide 1,6diacetate [1H NMR (CDCl₃) 1.38 ppm (6 H, s), 2.06 (6 H, s); α_D +44° (c 0.02, CHCl₃)] was successfully obtained from degradation product 11 in 7 steps [(1) NaOMe/MeOH/room temperature, (2) MeC(OMe)₂Me/Dowex-50X8-400/room temperature, (3) Pb(OAc)₄/C₆H₆-CH₂Cl₂/room temperature, followed by addition of MeMgI at room temperature, (4) Swern oxidation, (5) MCPBA/Na₂HPO₄/CH₂Cl₂/room temperature, (6) LiAlH₄/ THF/room temperature, (7) Ac₂O/Py] and also from the major product of osmium tetroxide oxidation of 31 in 8 steps [(1) MeC(OMe)₂Me/Dowex-50X8-400/room temperature, (2) H₂/Pd-C/AcOH-MeOH/room temperature, (3-8) same as steps 2-7 described above). The absolute configuration of this substance was confirmed to be 3R,4R on comparison of the optical rotation with that of the authentic sample (α_D +44.5° (c 0.44, CHCl₃)) prepared from (-)-diethyl D-tartrate in 8 steps [(1) MeC(OMe)₂Me/p-TSA/C₆H₆, (2) LiAlH₄/Et₂O, (3) TsCl/Py, (4) 2 N HCl/MeOH, followed by KOH workup, (5) CH₂=CHMgBr/CuI/Et₂O, (6) MeC(OMe)₂Me/p-TSA/acetone, (7) O₃/MeOH, followed by NaBH₄ workup, (8) Ac₂O/Py].

Stereochemistry of Palytoxin. 3.1 C7-C51 Segment

H. Fujioka, W. J. Christ, J. K. Cha, J. Leder, and Y. Kishi*

Department of Chemistry, Harvard University Cambridge, Massachusetts 02138

D. Uemura

Faculty of Liberal Arts, Shizuoka University Ohya, Shizuoka 422, Japan

Y. Hirata

Faculty of Pharmacy, Meijo University Tempaku, Nagoya 468, Japan Received July 19, 1982

For investigation of the configuration of C7-C51 of palytoxin,² degradation products 1-5 (Chart I) were available.³ Of these, 5 deserves special comment. Hirata, Uemura, and their co-workers established its structure, including the absolute configuration, by X-ray analysis.4 We have recently developed a practical, stereoselective synthetic route from (S)-(-)-citronellal to the optically active bicyclic acetal alcohol 6,5,6 which provided a solid foundation to study the stereochemistry of C18-C51.

First, we worked with degradation product 4. The ¹H NMR data suggested that the relative stereochemistry between C43 and C44 was as shown in 4.7 Routine synthetic operations allowed

(4) See ref 2c in part 1 of this series.

Chart I

the transformation of 6 (Chart II) into aldehyde acetate 7.8,9 Wittig reaction of 7 with phosphonium salt 8,9 followed by hydrogenation-hydrogenolysis and acetylation, gave pentaacetate **4** [1 H NMR ($C_{6}D_{6}$) δ 0.88 (3 H, d, J = 6.5 Hz), 1.08 (3 H, d, J = 6.8), 1.17 (3 H, s), 1.72 (3 H, s), 1.77 (6 H, s), 1.84 (3 H, s), 1.89 (3 H, s); α_D +54° (c 0.85, CHCl₃)]. Upon comparison of the spectroscopic data and optical rotations, the synthetic substance was found to be identical with degradation product 4, establishing the stereochemistry at C43 and C44.

Having already determined the stereochemistry at C49 and C50,1 we next studied the configuration at C45 and C46. NMR studies on degradation products 2 and 3 suggested that the stereochemistry at these centers was most likely as shown in 1.7 This assignment was confirmed by the following experiments.

Aqueous acetic acid treatment of $cis-\alpha,\beta$ -unsaturated ketone 99 (Chart III) resulted in the formation of a 3:2 mixture of two unsaturated spiro-6,6-ketals, 10a, and 10b, whose structures differed only in their configurations at the spiro center. Acetylation of the major isomer 10a followed by OsO₄ oxidation and acetylation yielded a single tetraacetate. Since one face of the olefinic bond of acetylated 10a was more sterically hindered, structure 11 was tentatively assigned to this product. This assignment was confirmed by further experiments utilizing $\operatorname{cis-}\alpha,\beta$ -unsaturated
