yield<sup>5</sup> and the N<sub>2</sub>O absorption cross section is very large.<sup>6</sup> The lamp is operated at a frequency of 100 Hz, with equal on and off times, and measurements are made of the decay time, following lamp turnoff, of the 5577 Å emission arising from the O(<sup>1</sup>S) → O(<sup>1</sup>D) + hν transition.

The quenching rate coefficient for the reaction

is obtained from a plot of decay time constant versus [N<sub>2</sub>O], the rate at which O(<sup>1</sup>S) is lost in the system being simply the sum of all losses. Thus, τ<sup>-1</sup>, the decay time constant, is

$$\tau^{-1} = k_1[\text{N}_2\text{O}] + \tau_R^{-1} + L, \quad (2)$$

where τ<sub>R</sub><sup>-1</sup> is the O(<sup>1</sup>S) reciprocal radiative lifetime, which depends on carrier gas pressure (because of collision-induced emission), but is in any case negligible compared with the other two terms, while L is the O(<sup>1</sup>S) loss rate caused by impurities and diffusion. A plot of τ<sup>-1</sup> versus [N<sub>2</sub>O] thus has an intercept of L and a slope of k<sub>1</sub>.

The data taken at three cell temperatures are shown in Fig. 1. The most recent value<sup>5</sup> for k<sub>300</sub> is (8.7 ± 0.9)

× 10<sup>-12</sup> cm<sup>3</sup> molecule<sup>-1</sup> sec<sup>-1</sup>, which agrees extremely well with the present data. The lines through the points are least square fits.

Figure 2 presents an Arrhenius plot of the data (the error bars are one standard deviation), from which one obtains the expression

$$k_1 = (3.8 \pm 1.0) \times 10^{-11} \exp[(-840 \pm 150)/RT] \\ \text{cm}^3 \text{ molecule}^{-1} \text{ sec}^{-1}.$$

The error limits in the pre-exponential term and in the activation energy must be utilized simultaneously. The products of this reaction have not yet been determined.

## Infrared matrix study of reactions of UF<sub>4</sub> with fluorine

K. R. Kunze, R. H. Hauge, D. Hamill, and J. L. Margrave

Department of Chemistry, Rice University, Houston, Texas 77001  
(Received 10 May 1976)

The technique of codeposition of various species onto an observation surface from the gas phase lends itself to the study of uranium tetrafluoride, which is adequately volatile. At temperatures of about 750 °C and a pressure of 10<sup>-6</sup> mm Hg, a sufficient amount of UF<sub>4</sub> will volatilize to enable one to deposit an observable amount in a matrix of argon. Deposition of UF<sub>4</sub> in matrices ranging in composition from pure fluorine to 0.001 mole fraction of F<sub>2</sub> in argon resulted in production of UF<sub>6</sub> and UF<sub>5</sub>, the relative intensities of their respective ir bands depending on the concentration of fluorine in the matrix.

The matrix isolation system used has previously been described elsewhere.<sup>1</sup> UF<sub>4</sub> was used as obtained from Research Organic/Inorganic Chemical Corporation. Technical grade fluorine from Air Products Corp. and research grade argon from Matheson were used as matrix materials. The UF<sub>4</sub> was of 98% reported purity and was comprised entirely of the U<sup>238</sup> isotope.

UF<sub>4</sub> was vaporized at 750 °C from an external furnace interfaced with the matrix surface to eliminate the possibility of F<sub>2</sub> dissociation to atoms on the hot surfaces. Fluorine and argon were premixed in a fluorine passivated aluminum container which was on line to the matrix. During codeposition, a matrix gas pressure of 2.0 × 10<sup>-5</sup> mm Hg was maintained. All trappings were

done for 1 h at a matrix temperature of 13 °K, the ir spectra being taken immediately after trapping.

It was found that essentially all of the UF<sub>4</sub> had reacted upon codeposition with pure fluorine as a matrix material. The UF<sub>4</sub> bands observed at 531 cm<sup>-1</sup> in a pure argon matrix were not apparent.<sup>2</sup> A new, intense band at 620 cm<sup>-1</sup> appeared in the spectrum, which has been assigned to UF<sub>6</sub>.<sup>4</sup> Gas phase UF<sub>6</sub> spectra have been reported to give a strong band at 626 cm<sup>-1</sup>.<sup>3</sup> The displacement from the gas phase value is attributable to matrix interaction with the UF<sub>6</sub> molecule. Upon successive dilution of the matrix (fluorine with argon), at mole fractions of 0.1, 0.01, and 0.001, two new peaks appeared at 560 and 584 cm<sup>-1</sup> which increased in intensity relative to the UF<sub>6</sub> peak as the fluorine concentration decreased (Fig. 1). These were assigned to UF<sub>5</sub> stretching modes, in agreement with the recent work of Paine *et al.*<sup>4</sup> One can also see that UF<sub>4</sub> modes begin to appear in the spectrum at lower F<sub>2</sub> concentrations, indicating incomplete reaction. The implication of these data is that F<sub>2</sub> does not add to UF<sub>4</sub> as an entire molecule, but rather donates one fluorine atom to the UF<sub>4</sub> as the other splits off. At high F<sub>2</sub> concentrations as in the pure F<sub>2</sub> matrix, there is a greater possibility that two F<sub>2</sub> molecules will each donate an F atom to the same UF<sub>4</sub> molecule to produce

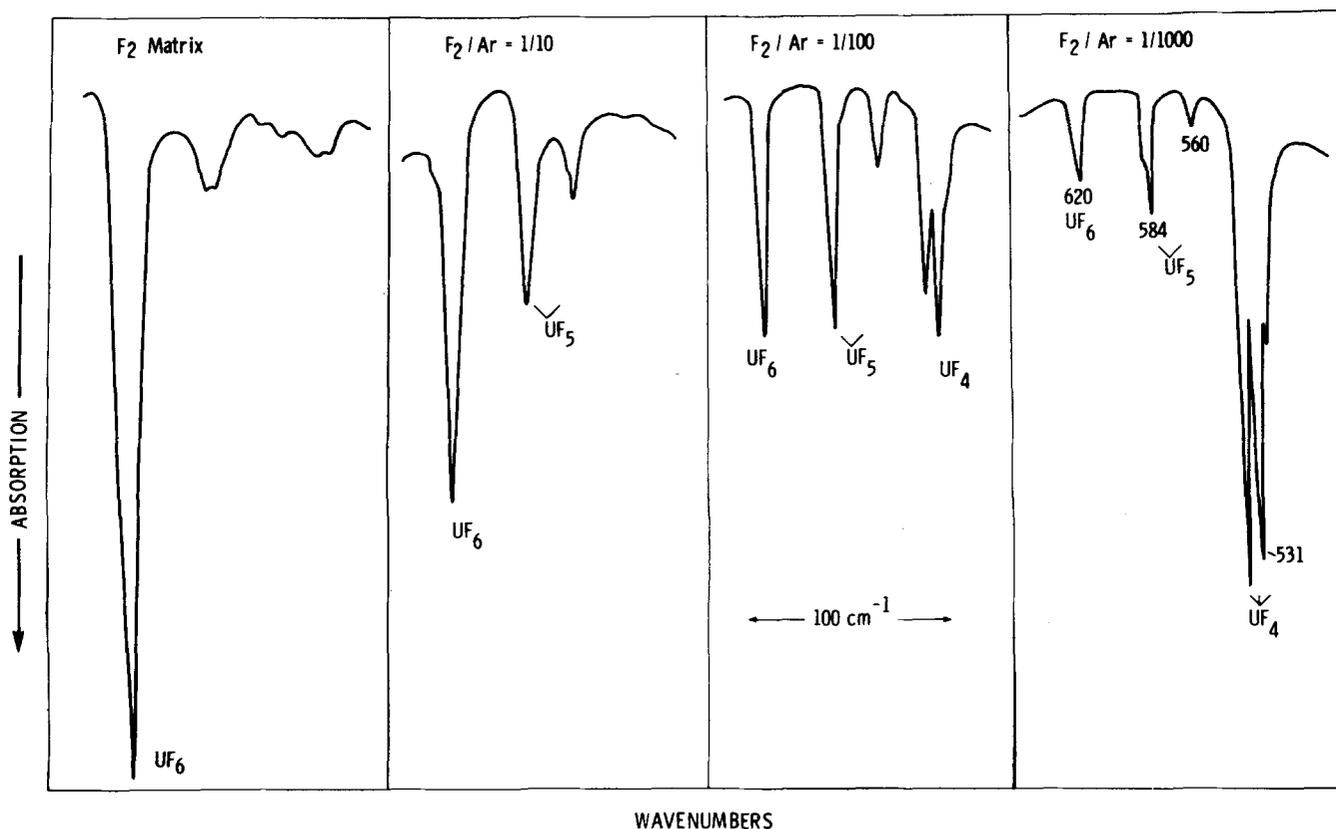

FIG. 1. Infrared spectra of  $\text{UF}_5$  and  $\text{UF}_6$  reaction products at several matrix fluorine concentrations.

$\text{UF}_6$ . At lower concentrations, however, a large percentage of the  $\text{UF}_5$  molecules, when formed, are not in the immediate vicinity of another  $\text{F}_2$  molecule. The reaction stops with  $\text{UF}_5$  formation in these cases.

The isolated gas phase  $\text{UF}_5$  structure has not been resolved at this stage of investigation. On the basis of group theory arguments, a trigonal bipyramidal structure ( $D_{3h}$ ) would give rise to two ir active stretching vibrations, one  $E$  and one  $A_2$  mode. A square pyramidal configuration ( $C_{4v}$ ) would have three ir active stretching modes, two  $A_1$  and one  $E$  type.<sup>4</sup> Our data are still inconclusive with respect to structure determination, as one of the bands for the square pyramidal configuration may be too low in intensity to be observed. Other workers<sup>4</sup> reported difficulty in resolving structure from combined Raman and ir studies, owing to a problem of obtaining  $\text{UF}_5$  in sufficient quantities in the matrix by photolysis of  $\text{UF}_6$ . Our method of  $\text{UF}_5$  production by direct reaction of  $\text{UF}_4$  with diluted fluorine may be a more efficient route to higher  $\text{UF}_5$  concentrations. The photolysis of  $\text{UF}_6$  in CO was reported to have produced a band at  $499\text{ cm}^{-1}$  attributable to either  $\text{UF}_4$  or polymers of  $\text{UF}_5$ .<sup>4</sup> A stable  $\text{UF}_4/\text{CO}$  adduct appears more likely in light of results obtained in this laboratory from the cocondensation of  $\text{UF}_4$  with CO, where a strong band at  $499\text{ cm}^{-1}$ <sup>12</sup> was also observed.

The existence of a  $\text{UF}_5$  intermediate in the production

of  $\text{UF}_6$  by direct fluorination of  $\text{UF}_4$  is in agreement with results obtained from bulk  $\text{UF}_4$  fluorination.<sup>5</sup> Previous workers have reported, however, that temperatures in excess of  $230^\circ\text{C}$  are required for a detectable amount of reaction to occur.<sup>5</sup> Our experiments indicate substantial  $\text{UF}_5$  and  $\text{UF}_6$  formation at temperatures of  $10\text{--}13^\circ\text{K}$ . One must keep in mind the different fluorination conditions between matrix and bulk fluorination. In the former, the  $\text{UF}_4$  molecules are essentially isolated from each other and free to react, whereas in bulk form the  $\text{UF}_4$  is in a lattice structure. It is clear from our results that reaction of an  $\text{F}_2$  molecule with a  $\text{UF}_4$  molecule occurs with essentially zero activation energy.
