# Aromatic Cyclodehydration. XVI.<sup>1</sup> Phenanthrene Hydrocarbons from Unsymmetrical Ketones

## BY CHARLES K. BRADSHER AND S. THOMAS AMORE

In the synthesis of phenanthrene hydrocarbons by the olefin oxide method, we have used as starting materials only aldehydes<sup>2a</sup> or symmetrical ketones.<sup>2b</sup> If unsymmetrical ketones (I) are used, it is obvious that the outcome of the dehydration reaction, and, by the same token, the structure of the ultimate phenanthrene derivative (III), will be unambiguous only in those cases in

which one group attached to the carbonyl contains no *alpha* hydrogen atom. Two ketones of sponding phenyl-*n*-propyl- and phenyl-*n*-decyl-phenanthrenes.

Of the unsymmetrical ketones having *alpha* hydrogens on both carbon atoms adjacent to the carbonyl, it was hoped that the methyl ketones (I,  $R = CH_3$ ) would form a special case. The carbinols derived from them might be expected to lose a hydrogen atom from the adjacent methylene group more readily than from the methyl, and the resulting olefin, upon oxidation and cyclization, would yield 9-methyl-10-alkylphenanthrenes.

It was found that while the olefin obtained from methyl ethyl ketone gave the expected 9,10-dimethylphenanthrene in 39% yield, the olefin from methyl *n*-amyl ketone gave 9-*n*-amylphenanthrene in almost comparable yield (31%), although some of the expected isomer may have been formed.

### Experimental

The general procedure was that described previously<sup>2b</sup> for the preparation of phenanthrene hydrocarbons from symmetrical ketones. The experimental data are recorded in the accompanying table.

TABLE I

### Summary

The olefin oxide type of cyclization has been applied to the synthesis of phenanthrene hydrocarbons from unsymmetrical ketones.
