□ A series of novel 2-C-methylribonucleosides, involving 5-iodo and 5-alkynyl uridine analogues as well as related bicyclic furano- and pyrrolo[2,3-d]pyrimidinone compounds, has been synthesized and evaluated for their inhibitory effect on replication of the hepatitis C virus (HCV). The new nucleoside analogues did not show meaningful anti-HCV activity.

INTRODUCTION

It has been shown that transformation of pyrimidine nucleosides into their bicyclic 6-alkyl-2,3-dihydrofurano[2,3-d]-pyrimidin-2(1H)-one or 6octyl-2,3-dihydropyrrolo[2,3-d]-pyrimidin-2(3H,7H)-one derivatives results in interesting biological properties. The type of biological activity, potency and selectivity, depend on structural factors: (1) structure of the sugar or pseudosugar moiety, and (2) the length of lipophilic alkyl substituent in the 6-position. Thus, the furanopyrimidine compounds are the most potent and selective inhibitors of varicella-zoster virus (VZV) as 2'-deoxynucleosides equiped with C_8 to C_{10} alkyl chains.^[1-3] In turn, 2'3'-dideoxynucleosides and their cyclopentyl analogues are not active against VZV but show selective and specific activity against human cytomegalovirus (HCMV).^[4]

Replacement of the 2-deoxyribofuranosyl moiety by the acyclovir-type 3-[(2hydroxyethoxy)methyl] chain considerably diminishes the antiviral properties of the furano [2,3-d]-pyrimidine system.^[5] On the other hand, it has been demonstrated that some analogous acyclonucleosides exhibit activity against human immunodeficiency virus (HIV) and herpes simplex virus (HSV) at micromolar concentrations.^[6] Further, SAR studies have indicated that furanopyrimidine nucleosides are, in general, more active than related pyrrolopyrimidine compounds.^[7] In turn, $3-(\beta-D-ribofuranosyl)$ -6-decyl-2,3-dihydrofurano[2,3-d]pyrimidin-2-on shows moderate anti-HCV activity in HCV replicon system and efficiently inhibits bovine viral diarrhea virus (BVDA).^[8a] More recently, a series of furano- and pyrrolo[2,3d]pyrimidine nucleoside 5'-O-triphosphates have been tested for their substrate properties toward some RNA and DNA polymerases to show that only the 6-hexylfurano compound is recognized by calf thymus terminal deoxynucleotidyl transferase (TDT) and HIV reverse transcriptase $(RT).^{[8]}$

From a synthetic viewpoint, furano[2,3-*d*]pyrimidine nucleosides can be efficiently prepared from the respective 5-iodouracil derivatives and alkynes under Sonogashira cross-coupling conditions. Depending on the temperature and the Pd-catalyst used, the reaction may proceed directly to fluorescent furano[2,3-*d*]pyrimidine products,^[9] or to intermediate 5-(alkyn-1-yl)uracil nucleosides.^[10] The latter compounds may then undergo an intramolecular cyclization to bicyclic furanopyrimidine nucleosides in a palladium-copper catalyzed reaction.^[1-8,10] The 5-(alkyn-1-yl)uracil nucleoside analogues demonstrate in vitro inhibitory activity against HSV-1, HSV-2, and vaccinia virus (VV).^[11] The related acyclonucleosides with 1-[(2-hydroxyethoxy)methyl] pseudosugar portion exhibit moderate anti-HIV activity,^[6] while the corresponding arabinofuranosyl, 2'-deoxy-2'fluororibofuranosyl, and 2',3'-dideoxyfuranosyl derivatives were found to be active against *Mycobacteria*.^[12,13]

In continuation of our study on the chemistry and biology of basemodified 2'-C- β -methylnucleosides,^[14,15] we synthesized a new series of 5-(alkyn-1-yl)uracil, furano[2,3-d]pyrimidine and pyrrolo[2,3-d]pyrimidine nucleosides, in order to evaluate the compounds for their antiviral properties. The 2'-C-branched nucleoside analogues are promising synthetic targets due to their potent antiviral activity against RNA viruses, including the hepatitis C virus (HCV). One of the most active compounds of this type is 2'-C- β -methylcytidine, a potent and selective inhibitor of the replication of *Flaviviridae* in cell culture.^[16–18] A number of its new derivatives modified within the sugar portion has been obtained, including 2'-deoxy-^[19,20] and 3'-deoxyribosides,^[21] 2'-C- β -methyl-1-(β -D-xylofuranoside,^[21] 2'fluoro^[22] and 3'-fluoro^[21] derivatives, the 3'-O-valyl ester,^[18] and the 3'methoxynucleoside.^[21] Modifications of the pyrimidine moiety have received relatively minor attention.^[14] Herein, we report the synthesis and antiviral evaluation of a novel series of 2'-C- β -methylribosides of 5-(alkyn-1-yl)uracil, furano[2,3-d]pyrimidine and pyrrolo[2,3-d]pyrimidine.

RESULTS AND DISCUSSION

The starting nucleoside synthon, tri-O-benzoyl-5-iodo-2'-C- β methyluridine (3) was obtained in the direct coupling reaction of 5-iodouracil (1) and 1,2,3,5-tetra-O-benzoyl-2-C-methyl- β -D-ribofuranose (2) under Vorbrüggen conditions (Scheme 1). Because 5-iodopyrimidine

nucleosides had never been synthesized in the 2'-C-branched series, we decided to include the compound in the antiviral screening. Therefore, the tri-O-benzoyl derivative **3** was deprotected with sodium methoxide in methanol (method A) or with methanolic ammonia (method B) to get 5-iodo-2'-C- β -methyluridine (**4**).

To prepare 5-alkynyl and furano [2,3-d] pyrimidine products, compound **3** was treated with 1-alkynes under the Sonogashira coupling conditions. Depending on reaction temperature and the nature of palladium catalyst used, we were able to obtain either 5-alkynyluridine analogues (**5**, **6**), or the bicyclic furano nucleosides (**9**, **10**). Thus, reaction of **3** with 1-decyne or 1-dodecyne in the presence of tetrakis(triphenylphosphine)palladium(0) [Pd(Ph₃P)₄] performed at room temperature gave the respective 5-decyn-1-yl (**5**) and 5-dodecyn-1-yl (**6**) nucleosides as main products. The tri-Obenzoyl derivtives **5** and **6** were then treated with methanolic ammonia to give nucleosides **7** and **8**.

In turn, the coupling reaction of **3** and 1-alkynes at higher temperature (80°C) and catalyzed by 10% Pd/C resulted in the formation of fluorescent, bicyclic 6-decyl and 6-dodecyl furanopyrimidine nucleosides (compounds **9** and **10**, respectively), which were deprotected to **11** and **12** by using methanolic ammonia. Interestingly, the use of sodium methoxide in methanol instead of NH₃/MeOH in an attempted debenzoylation of **9** resulted in an almost equimolar mixture of **11** and a new pyrimidine nucleoside, 4-O-methyl-5-(2-oxodecyl)-2'-C- β -methyluridine (**13**). The formation of **13** can be due to a nucleophilic attack of the methoxide anion at C7a of the furano[2,3-d]pyrimidine system and the subsequent ring opening. The ring-opening reaction is reversible. For instance, treatment of **13** with saturated solution of NH₃/MeOH at 50°C for 48 hours gave the pyrrolo[2,3d]pyrimidine derivative (**14**) as a single product. For a preparative scale, however, 6-octyl- and 6-decyl-pyrrolo[2,3-d]pyrimidine nucleosides (**14**, **15**) were prepared directly from the respective furano compounds (**11**, **12**).

The newly synthesized compounds: 5-iodo- (4) and 5-alkynyluridine analoges (5, 6), 6-alkyl furanopyrimidine nucleosides (11, 12), their 6-alkyl pyrrolopyrimidine congeners (14, 15), and ring-opened analogue (13) were examined using HCV subgenomic replicon system in Huh-5–2-cells. The compounds 4 and 13 were inactive as antiviral agents. The other nucleosides demonstrated low anti-HCV activity (EC₅₀ in the range of 31–85 μ M).

EXPERIMENTAL

General Procedures

1,2,3,5-Tetra-O-benzoyl-2-C- β -methyl- β -D-ribofuranose (**2**) was obtained.^[16] Melting points were determined on a Laboratory Devices Mel-Temp II micromelting points apparatus (Laboratory Devices, Holliston, MA, USA)

and are uncorrected. UV spectra were measured on a Beckman DU-65 spectrophotometer (Beckman, South Pasadena, CA, USA). The ¹H (300 MHz) and ¹³C NMR (75.5 MHz) spectra were recorded on a Varian Unity 300 FT NMR 300 MHz spectrometer (Varian, Palo Alto, CA, USA) in DMSO- d_6 with tetramethylsilane as an internal standard: chemical shifts are reported in δ -values (ppm), and coupling constants are given in Hz. High resolution mass spectra (HRMS) were taken on an AMD-604 spectrometer (AMD Intectra GmbH, Harpstedt, Germany) using the LSIMS technique (Cs⁺, 9 keV; in NBA). Thin-layer chromatography (TLC) was conducted on Merck silica gel 60 F₂₅₄ plates (E. Merck, Darmstadt, Germany) using the following solvent systems (measured by volume): A, chloroform-methanol (95:5); B, ethyl acetate-hexane (2:1); C, ethyl acetate-toluene (2:1). For preparative short-column chromatography Merck TLC gel H 60 was used.
