Studies of Phosphazenes. Part 14.¹ The Tautomerism of Oxocyclotriphosphazadienes

By K. S. Dhathathreyan, S. S. Krishnamurthy, and A. R. Vasudeva Murthy, Department of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore 560012, India

Robert A. Shaw and Michael Woods, Department of Chemistry, Birkbeck College (University of London), Malet Street, London WC1E 7HX

The tautomeric behaviour of 'monohydroxycyclotriphosphazatrienes' has been investigated by ³¹P n.m.r. spectroscopy. These derivatives exist as oxocyclotriphosphazadiene tautomers in which the hydrogen atom is attached to a ring nitrogen atom α to the phosphoryl group. Three types of prototropic behaviour are observed: (a) no exchange is detected and only one tautomer is present [e.g. N₃HP₃(NHBu^t)₂R₃O (R = OMe or OEt)]; (b) exchange takes place between two equivalent sites and only one tautomer is observed [e.g. N₃HP₃(NHBu^t)₂R₃O (R = OMe or OEt)]; (c) exchange takes place between two equivalent sites and only one tautomer is observed [e.g. N₃HP₃R₅O (R = OMe or OPh); N₃HP₃Ph₄RO (R = OMe or OEt)]; and (c) exchange occurs between two non-equivalent sites and two tautomers are present [e.g. N₃HP₃Ph₂R₃O (R = OMe, OEt, or OPrⁿ)]. It is shown that basicity calculations using substituent constants have predictive value since they are in good agreement with the spectroscopic observations.

CYCLOPHOSPHAZENE derivatives containing one or more hydroxy-substituents have been known since the nineteenth century 2-4 although many are poorly characterised.3 'Hydroxy' derivatives containing trifluoroethoxy- or aryloxy-groups have been reported in extensive studies of hydrolysis reactions by Allcock and Walsh.⁵ Derivatives of the types $N_3P_3Ph_2R_3(OH)$ and $N_3P_3Ph_4R(OH)$ (R = alkoxy) were obtained by Fitzsimmons et al.⁶ from alcoholysis reactions of the respective chloro(phenyl) precursors. It was suggested that these compounds exist in the oxocyclophosphazadiene form on the basis of their i.r. spectra. A similar conclusion was reached by Vîlceanu and Schulz ⁷ from an i.r. and ¹H n.m.r. study of the methoxy-derivative, N₃P₃(OMe)₅(OH). Recently, X-ray crystallography has confirmed the oxocyclophosphazadiene structure for the derivatives, N₃P₃- $Cl_2(NEt_2)_3(OH)$ ⁸ and $N_3P_3Ph_2(OMe)_3(OH)$.⁹

Four tautomeric structures are possible for a monohydroxycyclotriphosphazatriene, $N_3P_3R_3R'_2(OH)$ (Figure 1). In this paper, we show how dynamic ³¹P n.m.r. spectroscopy can be used to determine the preferred tautomers in solution for compounds of this type. We also evaluate the utility of pK_a' calculations in predicting the most likely tautomeric form of hydroxycyclophosphazenes containing different substituents.

EXPERIMENTAL

Preparations.—(a) gem-N₃HP₃(NHBu^t)₂(OMe)₃O (1).— The geminal bis(t-butylamino)-derivative, N₃P₃Cl₄(NHBu^t)₂ (5.0 g, 0.012 mol), was allowed to react with sodium methoxide as described previously.¹ After extraction of the methoxy-derivative, ¹ N₃P₃(NHBu^t)₂(OMe)₄, with light petroleum † the insoluble residue was dissolved in diethyl ether (200 cm³) and sodium chloride was filtered off. The filtrate was washed with dilute hydrochloric acid (100 cm³), sodium hydrogencarbonate solution (100 cm³), and water (3 × 75 cm³), dried (Na₂SO₄), and the solvent distilled off. The resultant oil solidified on addition of light petroleum. A further quantity of the same solid (i.r. evidence) was

† The fraction of b.p. 40-60 °C was used in each experiment.

obtained from the neutralised water washings by extraction with chloroform. Recrystallisation of the product from dichloromethane-light petroleum (1:5) gave 2,2,4-trimethoxy-4-oxo-6,6-bis(t-butylamino)cyclotriphosphazadiene

(1), m.p. 189—192 °C (2.8 g, 60%) (Found: C, 33.4; H, 8.0; N, 17.7. $C_{11}H_{30}N_5O_4P_3$ requires C, 33.9; H, 7.7; N, 18.0%). Molecular weight in benzene by osmometry = 701 (calc. 778). ¹H N.m.r. (CDCl₃): δ (NH) 7.5₀ (ring), 3.4; δ (OMe) 3.57(1), 3.68(2), ³J*(P-H) 12.4, 12.2 Hz; δ (CMe₃) 1.28.

(b) gem-N₃HP₃(NHBu^t)₂(OEt)₃O (2). The ethoxycompound (2) was prepared from N₃P₃Cl₄(NHBu^t)₂ (0.012 mol) and sodium ethoxide by the procedure given in (a). Extraction of the combined water washings with chloroform gave 2,2,4-triethoxy-4-oxo-6,6-bis(t-butylamino)cyclotriphosphazadiene (2), m.p. 194—196 °C (1.49 g, 35%) (Found: C, 38.8; H, 8.4; N, 15.9. C₁₄H₃₆N₅O₄P₃ requires C, 39.0; H, 8.3; N, 16.2%). ¹H N.m.r. (CDCl₃): δ (NH) 7.3₅ (ring), 3.1; δ (OCH₂) 3.92(1), 4.03(2), ³J*(P-H) 8.5, 8.5 Hz; δ (CMe₃) 1.36.

(c) gem-N₃HP₃Ph₂(OMe)₃O (8). The geminal bis(phenyl) derivative, N₃P₃Ph₂Cl₄ (5.0 g, 0.012 mol), was added to an excess of sodium methoxide and the mixture was heated under reflux for 4 h. This was diluted with diethyl ether (200 cm³) and filtered. The solution was washed with dilute hydrochloric acid (50 cm³), sodium hydrogencarbonate (50 cm³), and with water $(3 \times 50 \text{ cm}^3)$. The combined water washings (pH ca. 4) were extracted with chloroform using a continuous-extraction device. The solution was dried (Na_2SO_4) and the solvent removed. The residual oil solidified on addition of light petroleum (b.p. 40-60 °C). Recrystallisation from dichloromethane-light petroleum (1:4) 2, 2, 4-trimethoxy-4-oxo-6, 6-diphenylcyclotriphosphazagave diene (8), m.p. 185-187 °C (2.7 g, 58%) (Found: C, 45.0; H, 5.2; N, 10.3. C₁₅H₂₀N₃O₄P₃ requires C, 45.1; H, 5.0; N, 10.5%). Molecular weight in benzene by osmometry = 778 (calc. 795).

(d) gem-N₃HP₃Cl₂(NEt₂)₃O (3), gem-N₃HP₃Ph₂R₃O [R = OEt (9) or OPrⁿ (10)], gem-N₃HP₃Ph₄RO [R = OMe (6) or OEt (7)], and N₃HP₃R₅O [R = OMe (4) or OPh (5)]. These oxocyclotriphosphazadienes were obtained by the literature procedures described by Shaw and co-workers ^{6,8} and by Vîlceanu and Schulz.⁷

RESULTS AND DISCUSSION

The type of ³¹P n.m.r. spectrum expected for the tautomeric forms of $N_3P_3R_3R'_2(OH)$ (Figure 1) is easily predicted. A summary is given in Table 1. If protonation occurs at a ring nitrogen α to the phosphoryl group

the hydroxy-form: cases (d)—(i) in Table 1 are thereby excluded.

The ³¹P n.m.r. spectra of the t-butylamino-derivatives, gem-N₃HP₃(NHBu^t)₂R₃O [R = OMe (1) or OEt (2)], each consist of 12 lines (ABX pattern) at ambient temperature. The spectrum of the methoxy-derivative (1) is shown in Figure 2. The form of the spectrum remains unchanged at either 100 or -40 °C. This behaviour is only consistent with protonation at an α -ring nitrogen

[structures (II) and (III)], it is possible to distinguish cases (a), (b), and (c) in Table 1, even without a full analysis of the spectra or any knowledge of the n.m.r. parameters. If protonation occurs at the γ ring nitrogen atom or if the hydroxy-form of the compound

and with the absence of any exchange [Table 1(*a*)]. The chemical shifts (δ_p) and coupling constants $[^2J(P-P)]$ are shown in Figures 2 and 3 and clearly indicate that compounds (1) and (2) exist as the tautomeric form (II)

is present [structures (IV) and (I) respectively], the spin system is indistinguishable and some knowledge of the trends in chemical shifts and coupling constants for oxocyclotriphosphazadienes and cyclotriphosphazatrienes is essential. From a consideration of their ³¹P n.m.r. spectra, we can quickly establish that the compounds studied here do not exist either as the γ tautomer or as

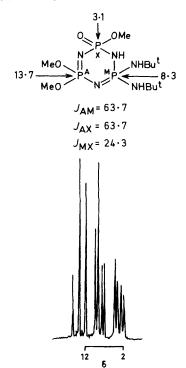

FIGURE 2 The ³¹P-{¹H} n.m.r. spectrum of $N_3HP_3(NHBu^t)_2$ -(OMe)₃O (1) in CDCl₃ at ambient temperature. Assignments of δ_P and ²J(P-P) (Hz) are indicated on the structure

in solution, *i.e.* the proton resides on the ring nitrogen atom adjacent to the =PRO and $\equiv P(NHBu^{t})_{2}$ groups.

The above observation is not difficult to rationalise. It has been shown earlier ¹⁰ that substituent constants $\alpha_{\rm R}$ and $\gamma_{\rm R}$ can be derived from the extensive basicity data available for cyclotriphosphazatriene derivatives. If

 $5.6-6.0.^{10}$) A more detailed discussion on this point is given elsewhere.¹¹

A typical basicity calculation, viz. for the conjugate base of N₃HP₃(NHBu^t)₂(OMe)₃O (1), is shown below; the α tautomeric form (II) is favoured and the agreement with the spectroscopic findings is excellent. In the case

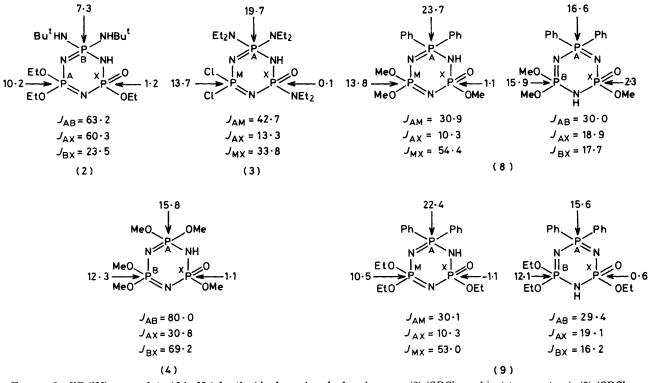

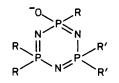

FIGURE 3 ³¹P-{¹H} n.m.r. data (J in Hz) for the 'hydroxy '-cyclophosphazenes, (2) (CDCl₃, ambient temperature), (3) (CDCl₃, ambient temperature), (4) (CD₂Cl₂, -95 °C), (8) and (9) (CDCl₃; -50 and -40 °C respectively)

the conjugate base of a 'hydroxy'-cyclophosphazene (shown below) is considered, the concept of substituent constants can be used to predict the preferred site(s) of protonation. It is not necessary to make assumptions regarding the value of α_{O^-} in order to calculate the relative basicities of the tautomeric forms in which protonation occurs at either ring nitrogen α to the \equiv PR(O⁻) group [Figure 1, structures (II) and (III)]. However, in order to predict the likelihood of the γ tautomeric form (IV) competing with either (or both) α forms, values of

 α_{O^-} and γ_{O^-} must be included in the calculation. There are no direct experimental measurements for these substituent constants and their magnitude must be assumed. Values of $\alpha_{O^-} = 6.0$ and $\gamma_{O^-} = 3.0$ appear appropriate as it is anticipated that an O⁻ substituent should be at least comparable to an amino-substituent in its electron-releasing capability. (The latter have α_R in the range

of the diethylamino-derivative, $N_3HP_3Cl_2(NEt_2)_3O$ (3), there is an equally convincing correlation. The α tautomeric form observed in solution by ³¹P n.m.r. spectroscopy (Figure 3) is clearly predicted by the basicity calculation (Table 2); protonation at the ring nitrogen α to =P(NEt_2)O and to =P(NEt_2)_2 is also observed in the solid state.⁸

sites is exhibited by the penta-alkoxy(aryloxy)-derivative, $N_3HP_3R_5O$ [R = OMe (4) or OPh (5)]. The ³¹P n.m.r. spectra of the phenoxy-compound (5) at ambient temperature and at -84 °C are illustrated in Figure 4. At the lower temperature, exchange is 'frozen' and a 12-line ABX spectrum is observed as the chemical n.m.r. spectrum of the methoxy-compound (6) at ambient temperature consists of three groups of signals: two doublets $[\delta(PPh_2) \ 24.0, \ ^2J(P-P) = ca. \ 4 \ Hz; \ 18.0, \ ^2J(P-P) = ca. \ 18.0 \ Hz]$ and two overlapping doublets, $\delta[PO(OMe)] \ -2.1$, are observed. Unfortunately, the quality of this spectrum is very poor owing to the ex-

shifts of the phosphorus nuclei of the two $\equiv P(OPh)_2$ groups now differ. At ambient temperature, exchange is fast, the above nuclei become equivalent, and an AX₂ spectrum is obtained. The methoxy-analogue (4) exhibits similar behaviour in its ³¹P n.m.r. spectrum. {Data obtained at -95 °C are shown in Figure 3; at ambient temperature $\delta[P(OMe)_2] = 14.9$, $\delta[PO(OMe)] =$ 2.1, 2/(P-P) = 48.8 Hz.}

The derivatives, $N_3HP_3Ph_4RO$ [R = OMe (6) or OEt (7)] should also provide examples of the above exchange phenomenon [Table 1, case (b)]. For example, the ³¹P

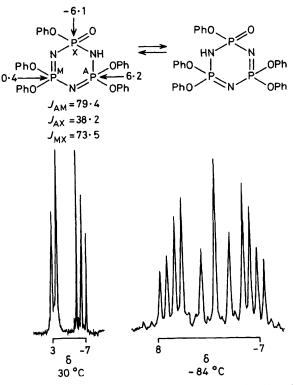

FIGURE 4 The ³¹P-{¹H} n.m.r. spectrum of N₃HP₃(OPh)₅O (5) in CDCl₃ (ambient temperature) and in CD₂Cl₂ (-84 °C). N.m.r. parameters (J in Hz) are indicated on the structural diagrams

tremely low solubility of compound (6) [and also of the ethoxy-analogue (7)] in organic solvents. Nevertheless, it is interesting to note that the exchange of the proton between equivalent α sites is very slow for the tetraphenyl compound, N₃HP₃Ph₄(OMe)O (6), even at ambient temperature. This slow exchange is presumably linked to the bulkiness of the four phenyl substituents.

The third kind of behaviour involving only α tautomers is that in which exchange occurs between two non-equivalent sites. The phenyl(alkoxy)-derivatives, N₃H-P₃Ph₂R₃O [R = OMe (8), OEt (9), or OPrⁿ (10)], provide examples of this tautomeric behaviour. At ambient temperature, their ³¹P n.m.r. spectra consist only of broad, featureless absorption signals; at *ca*. -40 °C (slow exchange) two overlapping ABX spectra can be discerned, each of which arises from the presence of an α tautomeric form, and at 100 °C exchange is rapid and a single ABX spectrum is obtained. In the last spectrum, the chemical shifts of the phosphorus nuclei of \equiv PPh₂ and \equiv PR₂(R = alkoxy) groups and the coupling constants, ²J(P-P), are an approximate average of the values obtained for the individual α tautomers at low temperature.

The above points are illustrated in Figure 5, which shows the n.m.r. spectra and data for the n-propoxyderivative (10). The ³¹P n.m.r. data obtained at low temperature for the methoxy- (8) and ethoxy- (9) derivatives are given in Figure 3. A consideration of the $\delta_{\rm P}$ values for the different α tautomeric forms of these alkoxy-derivatives, N₃HP₃Ph₂R₃O, (8)-(10), is informative. The values of $\delta(PPh_2)$ differ markedly for each pair of tautomers and this feature may be a result of differences in the bonding in adjacent N-P-N ring segments {more phosphazane character [Figure 1, structure (II; R' = Ph)] or more phosphazene character [structure (III)]}. In contrast, $\delta(PR_3)(R = alkoxy)$ is almost identical for both tautomers, even though comparable bonding characteristics apply. Perhaps there is a conformational difference in these tautomeric forms that is influenced by the bulky ≡PPh₂ group. The n.m.r. data also reveal some interesting and somewhat unpredictable differences in the values of the coupling constant

1553

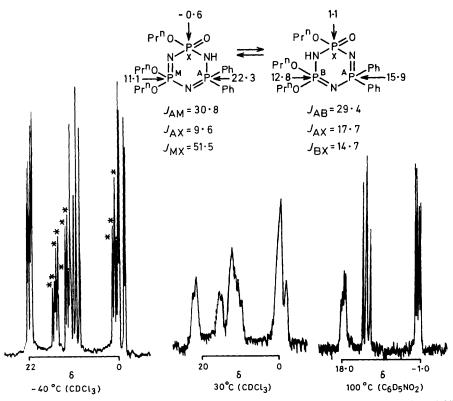

FIGURE 5 The ³¹P-{¹H} n.m.r. spectrum of N₃HP₃Ph₂(OPrⁿ)₃O (10) in CDCl₃ at ambient temperature and -40 °C [the ABX spectrum of the minor tautomer (III) is marked(*)] and in nitrobenzene (100° C). N.m.r. parameters (J in Hz) are indicated on the structural diagrams

²J(P-P). As anticipated from our recent study ¹ on sixmembered, cyclic phosphorus-nitrogen compounds containing one or more phosphazane linkages, the coupling across the phosphazane segment [=PR₂-N(H)-P(O)=] is always lower than that across either of the formal phosphazene segments. The large variation in the values of ²J(P-P) associated with phosphazene character may also depend markedly on conformational differences between each tautomeric form.

Basicity calculations for the alkoxy-derivatives (8)-(10) are given in Table 2. They correctly predict that the derivatives should exist in both α tautomeric forms and that the γ form is less favoured. It should be stressed that these calculations are approximate and that they are not intended to predict the absolute proportions of two α tautomers of similar basicity. For the alkoxy-compounds (8)--(10), ³¹P n.m.r. spectroscopy shows that the α tautomeric form (II) (Figure 1) predominates over form (III). The ratio is ca. 4:1 for the methoxy-derivative (8) and ca. 2:1 for the n-proposycompound (10). This increased proportion of tautomeric form (III) observed in solution for the n-propoxy-derivative, N₃HP₃Ph₂(OPrⁿ)₃O (10), undoubtedly reflects the greater base-strengthening effect of the n-propoxy-group compared to that of the methoxy-group.¹⁰

Molecular-weight measurements show that the oxocyclotriphosphazadienes reported in this study are dimeric in solution and that they presumably retain the doubly hydrogen-bonded structure found in the solid.^{8,9} However, their dimeric nature does not affect the interpretation of the ³¹P n.m.r. spectra.

Compared to the informative structural data obtained from ³¹P n.m.r. spectra, ¹H n.m.r. spectroscopy is much less helpful for studying the tautomeric behaviour of these 'hydroxycyclophosphazenes.' In many cases, the complexity of the spectra prevents any detailed analysis. One feature of the spectra that can be utilised is the resonance arising from the proton attached to a ring nitrogen atom. This >NH signal occurs at low field (8 7.3-10.0). In the 270-MHz n.m.r. spectrum of the methoxy-derivative, N3HP3Ph2(OMe)3O (8), recorded at -40 °C, two sharp >NH signals at δ 9.8 and 9.4 (in the ratio 4:1) are observed, thereby confirming the ratio of the tautomers (albeit not the precise structural assignment) obtained by ³¹P n.m.r. spectroscopy. Only four methoxy-doublets are clearly resolved at -40 °C: the ones at lower field (δ 3.37 and 3.52) arise from the =P(OMe)O group of tautomeric forms (II) and (III) respectively

Conclusions.—This study has demonstrated the following salient features. The oxocyclotriphosphazadienes investigated exist in solution as tautomers in which the hydrogen atom is bonded to a ring nitrogen atom α to the phosphoryl group. There is no evidence for γ tautomers or for the *P*-hydroxy-form. The preferred α tautomer(s) is readily established from the appearance and detailed analysis of the ³¹P n.m.r. spectrum at different temperatures. Calculation of the relative basic character of ring nitrogen atoms by utilising substituent constants provides a good correlation with the spectroscopic data. Thus, the combination of dynamic ³¹P n.m.r. spectroscopy and the predictive value of basicity calculations is a powerful one and should prove useful in gaining a further insight into the complex hydrolysis reactions^{3,4} of cyclophosphazene derivatives.

We thank the Overseas Development Administration, U.K., and the University Grants Commission, India, for support; U.L.I.R.S. (Kings College, London) for ³¹P n.m.r. spectra and the Bangalore n.m.r. facility for 270-MHz proton spectra. We gratefully acknowledge generous gifts of chlorocyclophosphazenes from the Ethyl Corporation, U.S.A., and BASF, Ludwigshaven. One of us (S. S. K.) is indebted to the British Council for a grant-in-aid to visit the United Kingdon, which enabled us to complete the writing of this paper.
