Abstract: A series of new polysubstituted derivatives of 2-tetralones possessing two ester 1 groups were synthesized via a tandem aldol condensation-Diels-Alder-aromatization 2 sequence of reactions. All the three steps took place in one pot and in the presence of 3 aminofunctionalized silica coated Fe₃O₄ nanoparticles as the catalyst. In situ formed dienes 4 reacted with diethyl acetylenedicarboxylate at room temperature and the process was followed 5 by spontaneous aromatization of the cycloadducts to produce high yields of the final tetralone 6 products. Further studies suggest that the process goes through an initial aldol condensation-7 cycloaddition sequence followed by oxidation and rearrangement steps. After completion of 8 the reactions, the catalyst could be recycled and reused efficiently in next reactions. 9 10 Key words: tandem reaction, tetralones, aldol condensation, Diels-Alder reaction, 11 12

aromatization.

3 Introduction 1 Tetralones constitute a group of organic intermediates which are used in the synthesis of 2 several biologically important compounds¹⁻³ or in the preparation of other chemicals such as 3 lipodioxigenase.⁴ substituted naphthols.⁵ or laser pigments.⁶ In addition, tetralone derivatives 4 are used in the synthesis of sertraline, a potent drug for the treatment of depression and 5 anxiety related problems.⁷ Different methods are reported for the synthesis of tetralones such 6 as intramolecular cyclization of phenylbutyric acid,⁸⁻¹⁰ reductive cleavage of naphthyl 7 ethers,¹¹ or the Haworth reaction.¹² 8 The [4+2] Diels-Alder (DA) cycloaddition is arguably one of the most versatile reactions in 9 synthetic organic chemistry and after almost one century from its discovery,¹³ the DA reaction 10still finds every day applications as the key step in the synthesis of important compounds,^{14,15} 11 intermediates,^{16,17} natural products,¹⁸ and pharmaceuticals.¹⁹ Nowadays, a fast growing and 12 interesting strategy involves the use of the DA reaction in tandem protocols^{20,21} for rapid and 13 efficient access to diverse libraries of complex products²² and target molecules.^{23,24} 14 In the framework of our studies on aldol condensation reactions, we have reported the 15 synthesis of a series of styrylcyclohex-2-enone dienes (e.g. 4a') in the presence of LiClO₄ and 16 TMSNEt₂ and under solvent-free conditions.²⁵ Subsequently, these dienes were explored for 17 their DA reactivities with N-phenylmaleimide,²⁶ methyl acrylate,^{21,27} and maleic 18 anhydride.^{21,28} The results led us to the synthesis of several derivatives of dehydrodecaline 19 skletone with different substitution patterns. In continuation of using heterogeneous 20 catalysts,^{29,30} here we introduce a new pathway for efficient synthesis of tetralone derivatives 21 via a tandem aldol condensation-DA-oxidative aromatization sequence, as exemplified in 22 Figure 1 for the synthesis of 4a. The whole process takes place in one pot by the use of 23 magnetically separable silica-coated functionalized nanoparticles of Fe_3O_4 (FN-Fe₃O₄). The 24 catalyst, which was prepared by using a known procedure,³¹ consists of a superparamagnetic 25

Page 4 of 17

core of iron oxide coated with silica and functionalized with 3-aminopropyl-triethoxysilane 1 and was used to produce a new series of polysubstituted tetralone derivatives. Consequently, 2 single products are obtained in high yields and the nanocatalyst is recoverable^{32,33} so that it 3 can be recycled into the next reactions without considerable loss of its efficiency. 4

Results and discussion

We first studied a model reaction by reacting enone 1 with 4-MeC₆H₄CHO (2a) and 10 dienophile **3a** under various sets of conditions (Table 1). Treatment of an equimolar mixture 11 of 1 and 2a with substoichiometric amounts of the catalyst followed by the addition of a 12 toluene solution of diethyl acetylenedicarboxylate (DEAD, 3a) led to 73% and 52% formation 13 of 4a under refluxing (entry 1) or 50 °C (entry 2) conditions, respectively. Repeating the 14 reaction without the catalyst gave no product and reactants were recovered entirely (entry 3). 15 To see if fully functionalized iron oxide particles are required to promote the reactions, some 16 amines were used, where lower quantities of 4a were obtained (entries 4-6). Search to find the 17 optimum solvent for the process supported that toluene can favour the highest conversion of 18 the reactants to 4a (entries 7-11). 19

To show the generality of the process, the optimized conditions were used to evaluate the 7 reactions of 1 with 3 and other aldehydes (Table 2). Therefore, benzaldehyde (entry 2) and its 8 derivatives bearing electron donating (entries 1 & 3-5) and electron withdrawing (entries 6-8) 9 substituents underwent a one-pot sequence of reactions with 1 and 3 to produce the respective 10 products 4 in good yields. All reactions were complete within 20-24 h and gave a derivative 11 of 4 as the major product of the process. 12

The structure of the products was elucidated by ¹H-NMR and ¹³C-NMR spectroscopic 5 methods. In the proton spectrum, the relative numbers of both aliphatic and aromatic protons 6 were diagnostic in determining the structure. In high field, signals consist of two ethoxy, two 7 equivalent geminal methyl, and two different methylene groups indicating the corporation of 8 reactants 3 and 1 in the structure of the product. On the other hand, besides the aromatic 9 protons of the aldehyde residue, the presence of an additional singlet aromatic proton at 10 slightly above 7.0 ppm was a strong indication for the aromatization of the final adduct. To 11 confirm the structure of the adducts, a single crystal of 4a was also prepared and subjected to 12 X-ray analysis. The results are depicted in Figure 2 and confirm the proposed structure. 13

2

Next, the recyclability of the catalyst was studied by using the recovered particles in the 4 model reaction (Figure 3, top). Thus, after completion of the process, the catalyst was 5 separated by using an external magnetic field (Figure 3, bottom) and reused in next reactions, 6 where it could be effective for at least additional 5 consecutive runs without showing 7 significant decrease in its performance.

Figure 3. Successful reuse of the catalyst.

It can be concluded from the results that the process initiates with an aldol condensation to 1 produce the respective diene 4' (Figure 4). The formation of the diene is then followed by a 2 DA cycloaddition with 3 so that 4" is formed. The final stabilizing rearrangement and 3 aromatization steps give the ultimate product 4. 4

Figure 4. Suggested reaction pathway.

In order to shed light on the mechanism of the process, derivatives of 4' were prepared 7 separately and when treated with 3 in refluxing toluene under atmospheric air pressure, the 8 expected products 4 were formed within 15-18 h. Moreover, when the addition of 1 to 3b and 9 4-MeC₆H₄CHO was conducted under inert atmosphere, the direct cycloaddition adduct 5 was 10 separated and characterized by ¹H-NMR spectroscopy. Then, this intermediate was 11 independently converted to 4d in refluxing toluene to further confirm the suggested pathway 12 of the reaction (Figure 5). 13

Conclusion

Experimental

General

In summary, we succeeded in developing a new procedure for the synthesis of polysubstituted 2 tetralone derivatives by using a one-pot procedure. As a result, the three reactants combine to 3 produce the desired products in high yields and the catalyst could be recovered and reused in 4 next reactions efficiently. We are planning to extend the results to the same reactions of 5 unsubstituted derivatives of 1 (3-methylcyclohex-2-enone) to evaluate the feasibility of 6 synthesizing polysubstituted naphthols (Figure 6). The study with other singly activated 7 dienophiles and heterodienophiles are also underway. 8

Melting points are uncorrected. FT-IR spectra were recorded using KBr disks on a Shimadzu 14 Prestige-21 spectrometer. NMR spectra were obtained on a FT-NMR Bruker Avance (300 15 MHz) or FT-NMR Bruker Ultra ShieldTM (500 MHz) as CDCl₃ solutions using Me₄Si as 16 internal standard reference. Elemental analyses were performed using a Thermo Finnigan 17 Flash EA 1112 instrument. MS spectra were obtained on a Fisons 8000 Trio instrument at 18 ionization potential of 70 eV. TLC experiments were carried out on pre-coated silica gel 19 plates using petroleum ether/EtOAc (4:1) as the eluent. Dienes 1 were synthesized using a 20 known method.²¹ All reagents and starting materials were purchased from commercial 21 sources. Aldehydes were redistilled or recrystallized before being used. All products are new 22 and were identified based on their physical and spectral properties. 23
