2-Allylphenol (1) constitutes a mixture of conformers, in which an $\mathrm{OH}-\pi$ hydrogen bonded closed (1a) and open form (1b) can be distinguished. 4-Substituted 2-allyphenols (2-9) have been synthesised and investigated by theoretical and spectroscopic methods. In $\mathbf{1 - 9}$, the energy and the structure of the hydrogen bonds show distinct variation with substituents. In the PE spectra of most compounds, two ionisations can be distinguished which are related to the allylic $\pi(\mathrm{C}=\mathrm{C})$ orbitals of the two conformers $\mathbf{a}$ and $\mathbf{b}$ and differ in energy by $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$. Alternatively, $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ can be determined indirectly from comparison of the PE spectra of the respective phenols and anisoles with the same substituents. $\Delta \operatorname{IP}(\mathrm{C}=\mathrm{C})$ values between 0.3 and 1.1 eV were found. Frequency shifts $\Delta v(\mathrm{OH})$ of the $\mathrm{O}-\mathrm{H}$ vibration in $\mathrm{CHCl}_{3}$ solution were measured by IR spectroscopy. By means of correlation analysis of the relationship between the strength of the intramolecular hydrogen bond, $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C}), \Delta v(\mathrm{OH})$ values and substituent constants it is established how substituents in 4-position affect the intramolecular $\mathrm{OH}-\pi$ hydrogen bond. The investigations demonstrate that the $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ data can be used as descriptors for this intramolecular interaction.

## Introduction

Hydrogen bonds are the most important intermolecular interactions. In biochemistry, pharmacy, crystallography, supramolecular chemistry, as well as in molecular recognition and selforganisation this kind of bonding plays a significant role. Weak hydrogen bonds have recently received considerable interest. ${ }^{1-3}$ Electron rich $\pi$-systems such as aromatic rings and carboncarbon double and triple bonds are the most important nonconventional acceptors in hydrogen bonding. For the first time, an $\mathrm{OH}-\pi$ hydrogen bond was detected by IR spectroscopy in 2-phenylphenol in solution in $\mathrm{CCl}_{4}$ by Wulff et al. ${ }^{4}$

Photoelectron spectroscopy (PES) has proved to be a valuable aid to the elucidation of the electronic structure of molecules. Brown was the first to prove the existence of intramolecular $\mathrm{OH}-\pi$ hydrogen bonds in syn-7-norbornenol ${ }^{5,6}$ and similar compounds by PES. In syn-7-norbornenol the $\pi(\mathrm{C}=\mathrm{C})$ ionisation shows a value approximately 0.2 eV higher than in the antiisomer. The energy difference is ascribed to the stabilisation of the $\pi(\mathrm{C}=\mathrm{C})$ MO by the hydrogen bond. On the other hand, the hydrogen bond causes a decrease in the $\mathrm{n}_{\pi}(\mathrm{O})$ ionisation by approx. 0.3 eV .

We have recently investigated intramolecular hydrogen bonds in various alkenols including 2 -allylphenol (1) by PES. ${ }^{7}$ In contrast to the compounds studied by Brown, ${ }^{5,6}$ 2-allylphenol shows conformational mobility, so that along with the H -bonded closed conformer 1a an open form 1b was found (Scheme 1). A strong ionisation band ( 10.01 eV ) is assigned to the allylic carbon-carbon double bond in the closed conformer, and a weak band $(9.72 \mathrm{eV})$ to that in the open conformer. A ratio of about $2: 1$ has been estimated from the relative intensities of these bands. ${ }^{7}$
The properties of 2 -allylphenol (1) can be varied widely by substituents in different positions, and such compounds offer excellent opportunities to study substituent effects on the intramolecular $\mathrm{OH}-\pi$ hydrogen bond by experimental

and theoretical methods. We have synthesised a series of 4-substituted 2-allylphenols by Claisen rearrangement from the corresponding allylphenylethers ${ }^{8-10}$ and investigated these compounds by means of PES and IR spectroscopy as well as by quantum-chemical calculations. As substituents the following groups have been chosen: $\mathrm{CH}_{3}, \mathrm{Br}, \mathrm{Cl}, \mathrm{OCH}_{3}, \mathrm{OC}_{2} \mathrm{H}_{5}, \mathrm{CN}$, $\mathrm{COCH}_{3}$, and $\mathrm{NO}_{2}$ (Scheme 1). Along with the phenols (1-9), their methyl ethers (anisoles) have been prepared as reference compounds without hydrogen bonds. PE spectra of the latter compounds were measured and their $\operatorname{IP}(\mathrm{C}=\mathrm{C})$ values relate to the allylic $\mathrm{C}=\mathrm{C}$ bonds undisturbed by hydrogen bonding. ${ }^{11}$

## Results and discussion

## Molecular structures and energies

Conformational analysis of 2-allylphenol (1) has been carried out by means of different spectroscopic and theoretical methods by Baker and Shulgin, ${ }^{12,13}$ Oki and Iwamura, ${ }^{14}$ Schaefer et al., ${ }^{15}$ Kim et al., ${ }^{16}$ as well as by Bosch-Montalvá et al. ${ }^{17}$ According to these investigations, the most stable conformer has a closed structure (1a) with a significant stabilisation by intramolecular

interaction between the allylic carbon-carbon double bond and the hydroxy group.

We have investigated the conformational properties of $\mathbf{1}$ by using the density functional theory (DFT) hybrid method B3LYP ${ }^{18,19}$ with the basis set $6-31+G^{* *}$. Of the many possible conformers the most stable three ( $\mathbf{1 a - 1 c}$ ) are depicted in Fig. 1. Some relevant structure and energy parameters of these conformers are summarised in Table 1. Their relative energies, including zero-point corrections, are 1a: $0.00, \mathbf{1 b}: 3.58$, 1c: $3.69 \mathrm{~kJ} \mathrm{~mol}^{-1}$. The most significant differences between $\mathbf{1 a}$ and $\mathbf{1 b}$ are the torsions of the hydroxy group and the allyl group relative to the benzene ring. While in $\mathbf{1 a}$ both parameters adopt values for favourable $\mathrm{OH}-\pi$ interaction, in $\mathbf{1 b}$ the opposite is true. This is expressed by the torsional angles $\varphi=(\mathrm{C}-2)-(\mathrm{C}-$ 1) $-\mathrm{O}-\mathrm{H}$ and $\eta=(\mathrm{C}-1)-(\mathrm{C}-2)-(\mathrm{C}-7)-(\mathrm{C}-8) ; \mathbf{1 a}: \varphi=20.6^{\circ}, \eta=$ $-60.3^{\circ} ; \mathbf{1 b}: \varphi=178.6^{\circ}, \eta=79.1^{\circ}$. For $\mathbf{1 a}$ this leads to distances of 231.6 and 249.6 pm between the hydroxy hydrogen atom and C-8 and C-9, respectively, of the allyl group. The corresponding distances between the latter atoms and the oxygen atom are 309.7 and 345.1 pm , respectively. These data compare well with those calculated for the methanol-ethene complex. ${ }^{20}$ However, in 1a there are some deviations from the "ideal" geometry of the $\mathrm{OH}-\pi$ hydrogen bond which can be expressed by the angles $\gamma$ and $\theta \cdot{ }^{20}$ The former angle defines the twist of the plane of the ethylene group with respect to the line between the hydroxy proton and the centre of the double bond $\left(\gamma=90^{\circ}\right.$ refers to an orthogonal orientation), and the latter angle defines the deviation from a straight line $\left(\theta=180^{\circ}\right)$ between the centre of the double bond and the hydroxy group. $\gamma$ and $\theta$ are close to 90 and $180^{\circ}$, respectively, in the methanol-ethene complex. In 1 a less favourable values $\gamma=69.3^{\circ}$ and $\theta=153.5^{\circ}$ are enforced by the molecular skeleton. X-Ray structure analyses of compounds $\mathbf{5}$, $\mathbf{6}$ and $\mathbf{9}$ indicate that in the crystalline state the molecules adopt conformations corresponding to $\mathbf{b}$, and the molecules are associated mainly by intermolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. ${ }^{21}$

The third conformer ( $\mathbf{1 c}$ ) is a second closed form with $\mathrm{OH}-\pi$ interaction. The main difference with respect to $\mathbf{1 a}$ is the torsion around the (C-7)-(C-8) bond in the allyl group. The corresponding dihedral angle $\tau=(\mathrm{C}-2)-(\mathrm{C}-7)-(\mathrm{C}-8)-(\mathrm{C}-9)$ has the values $126.3^{\circ}(\mathbf{1 a})$ and $-9.5^{\circ}(\mathbf{1 c})$, indicating that in 1a the allyl group adopts the anticlinal ( $+a c$ ) form while in $\mathbf{1 c}$ it is in the energetically less favourable synperiplanar ( $s p$ ) form. The structural data of $\mathbf{1 c}$ characterizing the $\mathrm{OH}-\pi$ hydrogen bond are comparable to those of 1a, however, a closer inspection indicates that $\mathrm{OH}-\pi$ interaction in $\mathbf{1 c}$ is somewhat less favourable than in $\mathbf{1 a}$.

Bosch-Montalvá et al. ${ }^{17}$ have estimated the strength of the hydrogen bond $\mathrm{OH}-\pi$ in 2 -allylphenol (1a) and related compounds by calculating the energy of the closed forms and comparing it with the result of a single point calculation for a structure with the $\mathrm{O}-\mathrm{H}$ bond in opposite orientation to the $\mathrm{OH}-\pi$ interaction. On the HF/6-31G ${ }^{* *}$ level of theory they obtained a value of $16.38 \mathrm{~kJ} \mathrm{~mol}^{-1}$. This value is essentially confirmed by the B3LYP method which in the same way gave $18.75 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for $\mathbf{1 a}$ and $15.25 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for $\mathbf{1 c}$. Recently, Korth et al. ${ }^{22}$ have criticised this approach. Their results demonstrate that the genuine strength of the intramolecular hydrogen bond of a phenolic compound cannot be unequivocally derived by simple rotation of the OH group into the "away" orientation, because additional steric and/or electronic 1,2 interactions may take place which are difficult or even impossible to separate from the sole H -donor/acceptor interaction.

Since for the investigated compounds $\mathbf{1 - 9}$ only minor structural differences are to be expected, in the present investigation we have used the energy difference of the closed conformer a and the open conformer $\mathbf{b}$ as an energetic measure of hydrogen bonding. We have only included these two most important conformers (analogous to 1a and 1b). The third (1c) can be considered as rather similar to $\mathbf{1 a}$ in its electronic properties, and accordingly it would be very difficult if not impossible to determine individual spectroscopic properties of this conformer that might be present in small amounts besides the other two.

For compounds $\mathbf{1 a - 9 a}$, it has been found that substitution in 4-position of the aromatic ring only slightly perturbs the structure parameters of the $\mathrm{OH}-\pi$ hydrogen bond. ${ }^{23}$ For all compounds the closed conformers a are more stable than the open forms $\mathbf{b}$. The energy differences are summarised in Table 2. They vary between $3.27 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (2) and $5.69 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (9), indicating a small but significant influence of the substituent on the strength of the hydrogen bond. Donor substituents weaken and acceptor substituents strengthen the $\mathrm{OH}-\pi$ interaction. This is indicated also by the distances between the hydroxy group and the allylic carbon-carbon double bond $[\mathrm{OH}-(\mathrm{C}-8) / \mathrm{C}(-9)$ and $\mathrm{O}-(\mathrm{C}-8) /(\mathrm{C}-9)]$ which is increased by the former and decreased by the latter type of substituents. ${ }^{23}$ The torsional angle $\varphi$ of the OH group with respect to the phenyl ring probably directly reflects the substituent effects: it varies between $16.7^{\circ}(\mathbf{9 a})$ and $25.7^{\circ}(\mathbf{3 a})$. As a general trend it can be stated that the acceptor groups enforce a more coplanar orientation of OH group and phenyl ring and as such strengthen the hydrogen bond, while donor substituents have the opposite effect.

Fig. 2 PE spectra of 4-substituted 2-allylphenols 1-9.

## PE spectra

The measured PE spectra are depicted in Fig. 2. The observed ionisation potentials of the investigated compounds are summarised in Table 3. The assignments of the IPs are based on B3LYP calculations, which were performed for conformers a and $\mathbf{b}$; the relevant results (orbital energies, calculated IPs, total energies of molecules and radical cations) are summarised in Tables 4 and 5. Assignments of the IPs can be achieved by using Koopmans' theorem, ${ }^{24} \mathrm{IP}_{i}=-\varepsilon_{i}$, by which vertical ionisation energies and SCF MO energies are related. Although KohnSham orbitals obtained by DFT methods ${ }^{25}$ are not SCF MOs and their physical meaning is still debated, it has been shown that they can be used with high confidence for the interpretation of PE spectra (see, e.g. ${ }^{26,27}$ ).
Much better agreement between experimental and theoretical values can be expected for the first vertical IP ( $\mathrm{IP}_{1 \mathrm{iv}}$ ) when the
energies of the molecule M and the radical cation $\mathrm{M}^{+}$are calculated. Since a vertical IP corresponds to the transition with the highest Franck-Condon factor without any structural change, a single point calculation is performed for $\mathrm{M}^{+}$using the molecule's geometry in order to obtain $\mathrm{IP}_{1 \mathrm{~V}}$. The corresponding energy values, which do not include any zero-point corrections, are given in Table 5 . We can now correct the other $\varepsilon^{\text {BBLYP }}$ values by the difference between $-\varepsilon(\mathrm{HOMO})$ and the calculated $\mathrm{IP}_{1 \mathrm{~V}}$ in order to obtain higher $\mathrm{IP}_{\mathrm{v}}$ values. ${ }^{27}$ Whereas for the compounds studied here energy differences between $\mathrm{IP}_{\mathrm{i}}$ and $-\varepsilon_{i}^{\text {BLLP }}$ values are 2.0 to 2.5 eV , experimental and calculated $\mathrm{IP}_{i}$ values differ only by 0.0 to 0.7 eV (average 0.3 eV ). Furthermore, both $-\varepsilon_{l}^{\text {B3LYP }}$ and calculated $\mathrm{IP}_{\mathrm{i}}($ calcd.) values are linearly correlated with the experimental $\mathrm{IP}_{i}$ (exp.) values with correlation coefficients ( $R^{2}=$ 0.990 and 0.987 ) close to 1.000 .

The IP values given in Table 3 have been assigned to ionisations of electrons from the MOs $\pi_{3}$ and $\pi_{2}$ of the aromatic ring,

to ionisations from the $\pi(\mathrm{C}=\mathrm{C})$ orbital of the allyl group and from an $n$ orbital of the hydroxy group and finally to ionisations from orbitals mainly localised on the substituent X. Such a classification is only approximate, since most orbitals are delocalised over the entire molecule. For compounds 1-6, individual IPs related to the allylic $\pi(\mathrm{C}=\mathrm{C})$ orbital could be identified in the spectra for conformers a (higher value) and $\mathbf{b}$. The two IPs differ by about $0.3-0.4 \mathrm{eV}$. This energy difference is explained by the intramolecular $\mathrm{OH}-\pi$ hydrogen bond. For the remaining phenols 7-9, because of band overlap the second (weak) IP could not be determined. Since the difference $\triangle \operatorname{IP}(C=C)$ of the $\operatorname{IP}(\mathrm{C}=\mathrm{C})$ values of the two conformers of compounds $\mathbf{1 - 9}$ is of essential importance for the present investigation (see below), we have estimated these values from the corresponding $\operatorname{IP}(\mathrm{C}=\mathrm{C})$ of the respective anisoles ${ }^{11}$ when direct measurement is not possible or inaccurate. For compounds 1-6, the exact position of the weak peak related to the "free" allylic carbon-carbon double bond (conformer b) was determined in several independent measurements, in some cases even at different temperatures, so that the accuracy of $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ is about $\pm 0.05 \mathrm{eV}$. Some of these spectra are supplied as electronic supplementary information (ESI) $\dagger$. In correlation analysis (see below) similar results are obtained, when $\Delta \operatorname{IP}(\mathrm{C}=\mathrm{C})$ is also determined for $\mathbf{1 - 6}$ with the aid of the corresponding anisoles.

## IR spectra

From the band shape and frequency of the $\mathrm{O}-\mathrm{H}$ stretching vibration measured by IR spectroscopy inter- and intramolecular hydrogen bonds can be distinguished by using a dilution series in non-polar solvents. ${ }^{2,28,29}$ Hydrogen bonds are characterised by a frequency shift $\Delta v_{\text {OH }}$ between the free and the associated hydroxy group. Baker and Shulgin ${ }^{12}$ have measured $\Delta v_{\text {OH }}$ values for several 2 -alkenylphenols including the parent compound 1 in $\mathrm{CCl}_{4}$ solution. The $\Delta v_{\mathrm{OH}}$ shifts were shown to depend on the basicity of the $\pi$ bond and on the geometrical configuration around the bonding groups. For 2-allylphenol (1), a gas phase IR spectrum displays two bands in the OH stretching region. ${ }^{17}$ The free $v_{\text {OH }}$ appears at $3650 \mathrm{~cm}^{-1}$, while the intramolecularly associated $v_{\mathrm{OH}}$ gives rise to a band at $3590 \mathrm{~cm}^{-1}$. These two values indicate a frequency shift characterizing the hydrogen bond of $\Delta v_{\mathrm{OH}}=60 \mathrm{~cm}^{-1}$.

Our measurements on compounds $\mathbf{1 - 9}$ were carried out in $\mathrm{CDCl}_{3}$ solution with concentrations of $0.7,0.07$ and 0.007 mol . The observed frequencies $v_{\mathrm{OH}}$ and frequency shifts $\Delta v_{\mathrm{OH}}$ are summarised in Table 6 together with the corresponding calculated data. As expected, ${ }^{25}$ the calculated values are larger than the experimental. Comparison of the data leads to a scale factor of about 0.94 for the calculated values. The experimental and calculated frequencies of the associated hydroxy groups are linearly correlated ( $R^{2}=0.931$ ), and the same holds for the $\Delta v_{\text {OH }}$ values ( $R^{2}=0.967$ ).

## Correlation analysis

In order to evaluate whether the $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ values determined by PE spectroscopy (Table 3) can be used as an indicator of
the strength of the hydrogen bond in a similar way as $\Delta v_{\mathrm{OH}}$ values, we have performed various linear correlation analyses. It has been found that indeed there is a fair linear correlation ( $R^{2}=0.867$ ) between $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ and the energy of the hydrogen bond as expressed by the $E_{\text {rel }}$ values (Table 2). In Fig. 3 the data points are depicted together with the correlation line and error limits ( $\pm 0.05 \mathrm{eV}$ ). For comparison, it is mentioned that between $E_{\text {rel }}$ and $\Delta v_{\mathrm{OH}}$ (exp.) as well as $\Delta v_{\mathrm{OH}}$ (calcd.) (Table 6) there is a satisfactory linear correlation $\left(R^{2}=0.975\right.$ for both) . Furthermore, fair linear correlations ${ }^{30}$ are observed between $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ and the $\mathrm{p} K_{\mathrm{a}}$ values ${ }^{31}$ of phenols $\mathbf{1 - 9}\left(R^{2}=0.836\right)$ and with the Hammett substituent constants $\sigma_{\mathrm{p}}{ }^{32}$ of the substituents in 4-position ( $R^{2}=0.803$ ). Again, these correlation coefficients are somewhat worse than for the $\Delta v_{\mathrm{OH}}$ values. $\Delta v_{\mathrm{OH}}$ (exp.) and $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ are also linearly correlated $\left(R^{2}=0.860\right)$. Thus, both can be used as a measure for the strength of the $\mathrm{OH}-\pi$ hydrogen bond in phenols. That $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ performs somewhat worse than $\Delta v_{\text {OH }}$, is probably caused by the rather small values and little variation of the former parameter.

Fig. 3 Correlation of relative energy $E_{\text {rel }}$ and $\Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ of 4-substituted 2-allylphenols 1-9.

Further correlations characterizing the hydrogen bond, in particular those between its energy and stereochemistry, have been published. ${ }^{23}$

## Conclusion

The weak intramolecular $\mathrm{OH}-\pi$ hydrogen bond in 4 -substituted 2-allylphenols is modified by the substituents in 4 -position. Acceptor groups clearly strengthen this interaction whereas donor substituents weaken it slightly. The strength of the hydrogen bond increases in the following order of substituents: $\mathrm{CH}_{3}<\mathrm{OC}_{2} \mathrm{H}_{5} \approx \mathrm{H} \approx \mathrm{OCH}_{3}<\mathrm{Cl}<\mathrm{Br}<\mathrm{CN}<\mathrm{COCH}_{3}<\mathrm{NO}_{2}$. In a similar way as IR frequency shifts $\Delta v_{\mathrm{OH}}, \Delta \mathrm{IP}(\mathrm{C}=\mathrm{C})$ values that are determined by PE spectroscopy from the ionisation potentials of the allylic carbon-carbon double bond in the free and in the associated conformer, can be used as indicators for the strength of the hydrogen bond.

## Experimental

Photoelectron (PE) spectra were recorded on a UPG200 spectrometer of Leybold-Heraeus equipped with a $\mathrm{He}(\mathrm{I})$ radiation source ( 21.21 eV ). Samples were evaporated directly into the target chamber. In order to obtain sufficient vapour pressure temperatures between 25 and $150{ }^{\circ} \mathrm{C}$ were used. The energy scale was calibrated with the lines of xenon at 12.130 and 13.436 and of argon at 15.759 and 15.937 eV . The accuracy of the measurements was approximately $\pm 0.03 \mathrm{eV}$ for ionisation energies, for broad and overlapping signals it was only $\pm 0.1 \mathrm{eV}$.

Infrared (IR) spectra were recorded at ambient temperature on a BIORAD FTIR spectrometer FTS135. The samples were dissolved in $\mathrm{CDCl}_{3}$ in cells with a length of $0.1,1.0$, and 10 mm with concentrations of $0.7,0.07$ and 0.007 mol , respectively. The accuracy of the measurements is about $\pm 1 \mathrm{~cm}^{-1}$.
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker Avance DRX 500 spectrometer. The following frequencies were used: $500.13 \mathrm{MHZ}\left({ }^{1} \mathrm{H}\right), 125.76 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. The spectra were measured as solution in a 5 mm tube at $25^{\circ} \mathrm{C}$ in the solvent $\mathrm{CDCl}_{3}$.

Becke3LYP (B3LYP) ${ }^{18,19}$ calculations were performed with the program GAUSSIAN $98 .{ }^{33}$ The basis set $6-31+G^{* *}$ was used, if not stated otherwise. Prior to quantum chemical calculations, molecular geometries were pre-optimised by molecular mechanics calculations using the $\mathrm{MMX}^{34}$ force field with the program PCMODEL. ${ }^{35}$
$\mathrm{p} K_{\mathrm{a}}$ values of phenols $\mathbf{1 - 9}$ have been retrieved from Chemical Abstracts using SciFinder Scholar. The data have been calculated using ACD software. ${ }^{31}$

## Materials

2-Allylphenol (1) and 4-acetyl-2-allylphenol (8) were purchased from Lancaster Synthesis GmbH, Mühlheim am Main, Germany. 4-Substituted 2-allylphenols have been prepared from the corresponding allyl-phenylethers by Claisen rearrangement. ${ }^{8,9}$ Syntheses of compounds $\mathbf{2},{ }^{9,36} \mathbf{3},{ }^{37} 5,{ }^{36} \mathbf{6},{ }^{38} 7,{ }^{39}$ and their spectroscopic characterisation have been described in the literature.

2-Allyl-4-ethoxyphenol (4). $\mathrm{Bp} 114{ }^{\circ} \mathrm{C} 2 \mathrm{mbar}^{-1}$ (lit. ${ }^{40} 184$ $185{ }^{\circ} \mathrm{C} 67 \mathrm{mbar}^{-1}$ ); ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 1.36(\mathrm{t}, J$ $\left.=7.0 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{ArOCH}_{2} \mathrm{CH}_{3}\right), 3.35(\mathrm{dt}, J=6.4 \mathrm{~Hz}, 1.5 \mathrm{~Hz}$, $\left.2 \mathrm{H} ; \mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right), 3.95\left(\mathrm{q}, J=7.0 \mathrm{~Hz}, 2 \mathrm{H} ; \mathrm{ArOCH}_{2} \mathrm{CH}_{3}\right)$, $4.61(\mathrm{~s}, 1 \mathrm{H} ; \mathrm{ArOH}), 5.11-5.16\left(\mathrm{~m}, 2 \mathrm{H} ; \mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right), 5.98$ $\left(\mathrm{m}, 1 \mathrm{H}, \mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right), 6.64(\mathrm{~d}, J=8.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH})$, $6.66(\mathrm{~s}, 1 \mathrm{H}, \mathrm{ArH}), 6.71(\mathrm{~d}, J=8.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}$ ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 14.93\left(\mathrm{CH}_{3}\right), 35.29\left(-\mathrm{CH}_{2}-\right), 63.97(\mathrm{O}-$ $\left.\mathrm{CH}_{2}\right) 113.34(\mathrm{C}-5), 116.44(\mathrm{C}-3), 116.51(\mathrm{C}-6), 116.72\left(=\mathrm{CH}_{2}\right)$, 126.40 (C-2), 136.18 (allyl-CH), 147.88 (C-1), 153.10 (C-4); IR $\left(\mathrm{CDCl}_{3}\right): v_{\max } / \mathrm{cm}^{-1} 3535\left(\mathrm{OH}_{\text {ass }}\right), 2982(\mathrm{C}-\mathrm{H}), 1653\left(\mathrm{C}=\mathrm{C}^{\text {al }}\right)$, $1505\left(\mathrm{C}=\mathrm{C}^{\mathrm{ar}}\right), 1203(\mathrm{C}-\mathrm{O})$.

2-Allyl-4-nitrophenol (9). Mp $77{ }^{\circ} \mathrm{C}$ (lit. ${ }^{9} 79{ }^{\circ} \mathrm{C}$ ); ${ }^{1} \mathrm{H}-\mathrm{NMR}$ $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 3.45\left(\mathrm{~d}, J=6.4 \mathrm{~Hz}, 2 \mathrm{H} ; \mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right)$, 5.18-5.25 (m, 2H; $\left.\mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right), 5.74(\mathrm{~s}, 1 \mathrm{H} ; \mathrm{ArOH}), 5.99$ (ddt, $J=16.9 \mathrm{~Hz}, 10.4 \mathrm{~Hz}, 3.9 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}$ ), $6.86(\mathrm{~d}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH}), 7.24(\mathrm{~s}, 1 \mathrm{H}, \mathrm{ArH}), 8.05(\mathrm{~d}, J$ $=7.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}\left(126 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 34.71(-$ $\left.\mathrm{CH}_{2}-\right), 115.86\left(=\mathrm{CH}_{2}\right), 118.08(\mathrm{C}-6), 124.03 .(\mathrm{C}-3), 124.87(\mathrm{C}-5)$, 126.39 (C-2), 134.57 (allyl-CH), 141.72 (C-4), 159.65 (C-1); IR $\left(\mathrm{CDCl}_{3}\right): v_{\max } / \mathrm{cm}^{-1} 3433\left(\mathrm{OH}_{\text {ass }}\right), 1609(\mathrm{C}=\mathrm{C}), 1522\left(\mathrm{NO}_{2}\right), 1342$ $\left(\mathrm{NO}_{2}\right), 1165(\mathrm{C}-\mathrm{O})$.
