### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

# Toward Direct Protein S-Persulfidation: A Prodrug Approach that Directly Delivers Hydrogen Persulfide

**ABSTRACT:** A general strategy of delivering hydrogen persulfide ( $H_2S_2$ ) is described herein. Esterase- and phosphatase-sensitive  $H_2S_2$  prodrugs with tunable release rates have been synthesized. Their utility is validated in examining protein S-persulfidation. With this unique approach of directly delivering  $H_2S_2$ , our findings reaffirmed that S-persulfidation leads to decreased activity of glyceraldehyde 3-phosphate dehydrogenase (GAPDH). This new approach complements available prodrugs/donors that directly deliver a single species including hydrogen sulfide, perthiol, and COS, and will be very useful as part of the toolbox in delineating the mechanisms of sulfur signaling.

Hydrogen sulfide ( $H_2S$ ) plays roles in physiological and pathological processes and has promising therapeutic potential.<sup>1-10</sup> Recent studies suggest that endogenous hydrogen polysulfides ( $H_2S_n$ ,  $n \geq 2$ ) and perthiol ( $RS_nH$ ,  $n \geq 2$ ) have similar physiological effects as  $H_2S$ , but with greater potency in some cases.<sup>11-15</sup> For example, hydrogen polysulfides were found to be able to induce  $Ca^{2+}$  influx by activating transient receptor potential (TRP)A1 channels in rat astrocytes and are 320 times more potent than  $H_2S$ .<sup>16</sup> Protein S-persulfidation (sometimes referred to as S-sulfhydration), in which the thiol group of cysteine (-SH) in protein is converted to a perthiol group (-SSH), has proven to be a major signaling pathway involving sulfur.<sup>17-20</sup> Many enzymes can go through this process, leading to significant changes in activity.<sup>19,21,15,22,17,23</sup> Chemically,  $H_2S$  cannot simply “persulfidate” a thiol group. Therefore, either some other oxidation reaction(s) needs to happen or the  $H_2S$  source contains sulfur species at higher oxidation states.<sup>15,24</sup> Thus, it is likely that hydrogen polysulfide and/or perthiol derived from  $H_2S$  are the actual dominant species in S-persulfidation.<sup>25-28</sup>  $H_2S$  and perthiol can be produced enzymatically.<sup>11,12,29</sup> The facts that hydrogen polysulfide and perthiol can lead to protein S-persulfidation and there are enzymatic pathways to produce such species lend further support to the possibility that hydrogen polysulfide and perthiol are the actual signaling molecules in certain processes.<sup>29</sup>

Given the significant role of hydrogen polysulfide and perthiol in protein S-persulfidation signaling, there is a need to prepare prodrugs for generating hydrogen polysulfide as single species without perturbing cellular redox chemistry. Several labs have reported beautiful work in preparing prodrugs for  $H_2S$ ,<sup>30-34</sup> perthiol,<sup>35</sup> and COS.<sup>31,36-39</sup> What are missing in the toolbox are prodrugs for  $H_2S_2$  as a

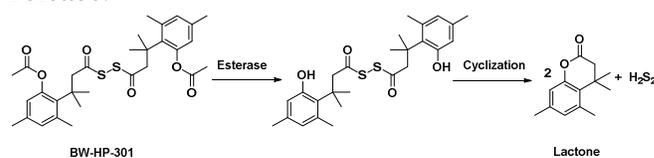

single or at least as a dominant species. Herein, we described our work in this regard.

## Scheme 1. The design concept of $H_2S_2$ prodrugs.

The need of developing  $H_2S_2$  prodrugs derives from its unstable nature.<sup>40</sup> We used the “trimethyl lock”-facilitated lactonization system as the caging group for prodrug preparation (Scheme 1).<sup>41</sup> Specifically,  $H_2S_2$  is caged as two thiolacid groups linked by a disulfide bond (Scheme 1). A masked phenol hydroxyl group serves as a latent nucleophile for initiation of  $H_2S_2$  release through lactonization.

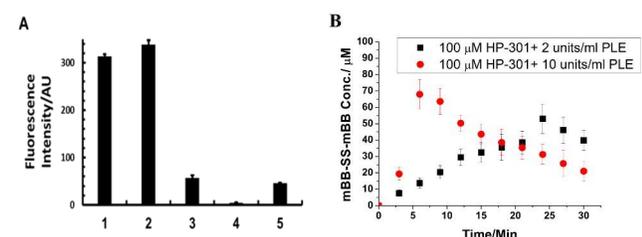

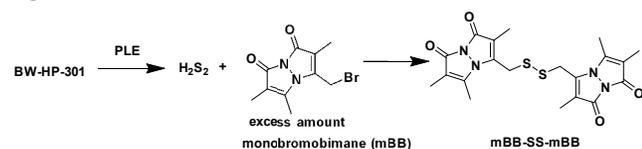

## Scheme 2. Mechanism of esterase-triggered $H_2S_2$ release.

An esterase-sensitive  $H_2S_2$  prodrug, **BW-HP-301** (**301**), was prepared (Scheme 2). **301** is a colorless oil and stable for days at room temperature and months at  $-20$  °C. We studied whether esterase would promote  $H_2S_2$  release from **301** using a  $H_2S_2$  fluorescence probe DSP-3.<sup>42</sup> Thus, **301** was incubated with porcine liver esterase (PLE) at 37 °C in phosphate-buffered saline (PBS, pH = 7.4) for 30 min to fully consume **301**; then 20  $\mu M$  of DSP-3 was added. Strong fluorescence was observed in experiments with PLE (Figure 1A), indicating the release of  $H_2S_2$ . In contrast, negligible fluorescence was detected without PLE. Incubation with 200  $\mu M$   $Na_2S$  led to negligible fluorescence intensity increase, showing the stability of DSP-3 toward  $H_2S$ . To provide further direct evidence of  $H_2S_2$  release, we used monobromobimane (mBB) to trap  $H_2S_2$  in a stable form, mBB-SS-mBB (Scheme 3 and Figure 1B).<sup>43</sup>  $68 \pm 8$   $\mu M$  of mBB-SS-mBB was detected from 100  $\mu M$  prodrug **301** in the presence of 10 unit/mL of PLE. The less than 100% conversion could be due to many reasons, including slow reaction kinetics and stability issues for  $H_2S_2$ . As a reference point, we also used the same method to trap  $H_2S_2$  from commercially available  $Na_2S_2$ . About  $71 \pm 9$   $\mu M$  of mBB-SS-mBB was detected in 100  $\mu M$  of  $Na_2S_2$  solution (Figure S2). The fact that the prodrug and  $Na_2S_2$  gave the same results in both

the DSP-3 and mBB assays strongly suggest that the release from the prodrug was nearly 100%. The efficiency of the H<sub>2</sub>S<sub>2</sub> trapping reaction was most likely the reason causing the less than 100% conversion to the trapped product, mBB-SS-mBB. It is important to note that H<sub>2</sub>S<sub>2</sub> concentration from the addition of 100 μM Na<sub>2</sub>S<sub>2</sub> started decreasing from the moment of dissolution (Figure S2). However, with 100 μM **301**, the H<sub>2</sub>S<sub>2</sub> concentration gradually increased with the addition of 2 units/mL PLE and reached a peak concentration at 25 min.

### Scheme 3. Direct detection of H<sub>2</sub>S<sub>2</sub> by trapping agent mBB.

**Figure 1.** A) Qualitative detection of H<sub>2</sub>S<sub>2</sub> release from **301** by DSP-3. **301** was incubated with 2 units/mL PLE in PBS (2% DMSO) for 30 min and then DSP-3 (20 μM) was added. Data were acquired at 515 nm with excitation at 490 nm. n = 3. 1) 100 μM **301** + PLE; 2) 100 μM Na<sub>2</sub>S<sub>2</sub> + PLE; 3) PLE; 4) 100 μM **301**; 5) 200 μM Na<sub>2</sub>S + PLE. B) Direct detection of H<sub>2</sub>S<sub>2</sub> by trapping agent mBB from **301** in PBS (2% DMSO). n = 3.

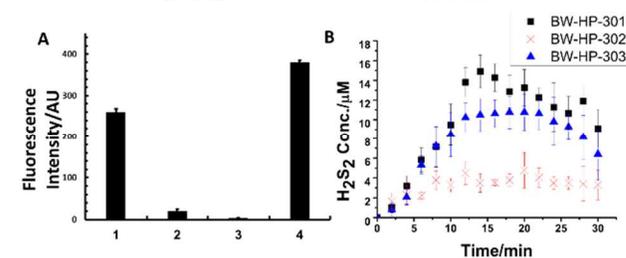

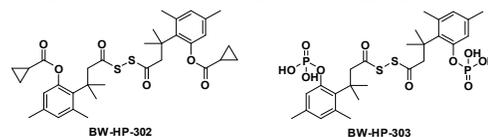

One would expect the sustained concentration of H<sub>2</sub>S<sub>2</sub> to be dependent on the release rate from a prodrug since the generation and consumption of thiol species in the biological system is a dynamic process. Thus, we wanted to prepare prodrugs with varying release rates. Specifically, **BW-HP-302** (**302**) was synthesized (Scheme 4) and its H<sub>2</sub>S<sub>2</sub> release ability was assessed (Figure S1). The H<sub>2</sub>S<sub>2</sub> release profiles from **301** and **302** are shown in Figure 2B. From 40 μM of the prodrugs, **301** had a peak concentration of 15 μM at around 15 min, while **302** maintained a sustained concentration of about 3 μM. The release profile of **302** was also studied by using mBB. A plateau of 35 ± 7 μM of mBB-SS-mBB was detected from 100 μM of **302** in the presence of 10 units/mL PLE (Figure S2). For 100 μM of the prodrug, the half-life was determined to be 24 min for **301** and 172 min for **302** by HPLC (Table S4). The slower release rate of **302** was presumably due to the bulkier nature of the cyclopropanecarbonyl ester, which hinders esterase-mediated hydrolysis.<sup>44</sup>

In an effort to broaden the tunability of H<sub>2</sub>S<sub>2</sub> release, a phosphatase-sensitive H<sub>2</sub>S<sub>2</sub> prodrug, **BW-HP-303** (**303**), was synthesized (Scheme 4). Alkaline phosphatase (ALP) is widely used for prodrug activation.<sup>45-47</sup> Phosphatase-dependent H<sub>2</sub>S<sub>2</sub> release was examined by DSP-3 (Figure 2A). Incubation of **303** with 10 units/mL ALP led to strong fluorescence, demonstrating H<sub>2</sub>S<sub>2</sub> release. In the absence of phosphatase, almost no H<sub>2</sub>S<sub>2</sub> was detected, indicating the chemical stability of the prodrug. A peak concentration of 65 ± 8 μM of mBB-SS-mBB was achieved from 100 μM **303** in the presence of 10 units/mL ALP. Such result is similar to that of 100 μM **301** and Na<sub>2</sub>S<sub>2</sub>, demonstrating the efficient H<sub>2</sub>S<sub>2</sub> release from **303** (Figure S2). From 40 μM **303**, a

peak concentration of 10 μM of H<sub>2</sub>S<sub>2</sub> was detected (Figure 2B) with a half-life of 28 min in the presence of 2 units/mL ALP (Table S4).

To assess the utility of the prodrug in delivering H<sub>2</sub>S<sub>2</sub> in biological systems, cells were co-treated with 100 μM **301** and PLE or 100 μM **303** and ALP (Figure S9), respectively. Strong fluorescence was observed, indicating H<sub>2</sub>S<sub>2</sub> release. No obvious cytotoxicity was found at up to 100 μM of the prodrugs or lactone on H9c2 cells after 24 and 48 h incubation (Figure S5,6).

### Scheme 4. Structures of **302** and **303**

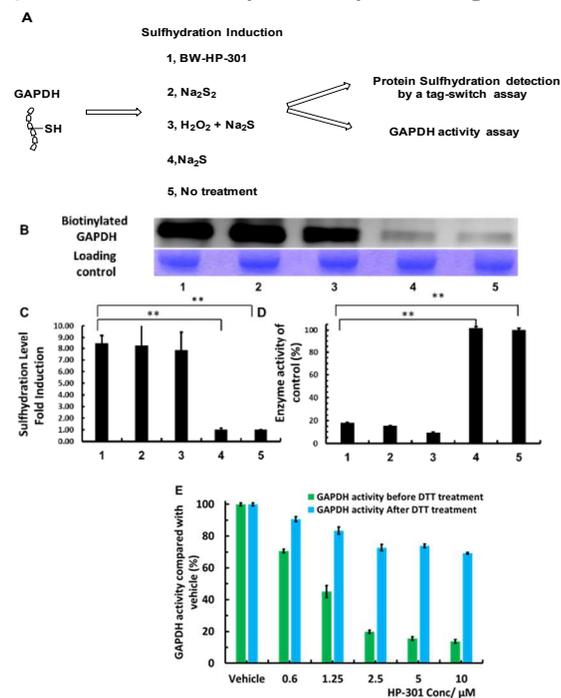

**Figure 2.** A) Qualitative assessment of H<sub>2</sub>S<sub>2</sub> release from **303** by DSP-3. The concentration of DSP-3 is 20 μM and ALP is 10 units/mL in PBS (1% MeOH). n = 3. 1) 100 μM **303** + ALP; 2) 100 μM **303**; 3) ALP; 4) ALP + 100 μM Na<sub>2</sub>S<sub>2</sub>. B) H<sub>2</sub>S<sub>2</sub> releasing profile from 40 μM **301** and **302** with 1 unit/mL PLE in PBS (2% DMSO) and **303** with 2 units/mL ALP at 37 °C in PBS (2% MeOH). 20 μM DSP-3 was used. n = 3.

S-persulfidation is a major sulfur signaling pathway.<sup>17-19</sup> We then examined the S-persulfidation efficiency of the prodrugs on GAPDH using a tag-switch assay.<sup>48</sup> Incubation with 100 μM **301** and 10 units/mL PLE at 37 °C led to a significant increase in GAPDH S-persulfidation level (Figure 3B and C, line 1) compared to the untreated group (line 5). In contrast, incubation with 200 μM H<sub>2</sub>S (line 4) failed to elevate GAPDH S-persulfidation level. Protein samples were also treated with 100 μM Na<sub>2</sub>S<sub>2</sub> or 100 μM H<sub>2</sub>O<sub>2</sub> followed by 100 μM H<sub>2</sub>S (line 2, 3) to mimic the two endogenous S-persulfidation process (Figure S10).<sup>15,48,49</sup> These two methods each led to a significant increase of GAPDH S-persulfidation level. Such results further affirm that H<sub>2</sub>S itself is incapable of protein S-persulfidation. Previously H<sub>2</sub>S has been shown to abolish S-persulfidation by itself.<sup>50</sup> The roles that H<sub>2</sub>S plays in S-persulfidation and signaling are dependent on ROS and cellular redox environment. However, **301** was able to induce S-persulfidation independent of ROS. These H<sub>2</sub>S<sub>2</sub> donors are important research tools to conduct S-persulfidation without perturbing the redox balance. Even with data suggesting H<sub>2</sub>S<sub>2</sub> being the dominant species released from **301**, we can't exclude the possibility that other polysulfide derived from H<sub>2</sub>S<sub>2</sub> degradation may also play a role in S-persulfidation because of the unstable nature of H<sub>2</sub>S<sub>2</sub>.

It has been a subject of debate as to whether S-persulfidation leads to increased or decreased activity of GAPDH.<sup>17,23</sup> To address this point, GAPDH was treated with the exact conditions that was used in the S-persulfidation assay above. Then enzyme activity was determined. As shown in Figure 3B and D, GAPDH treated with **301**, Na<sub>2</sub>S<sub>2</sub>, or H<sub>2</sub>S and H<sub>2</sub>O<sub>2</sub> together each showed elevated pro-

tein S-persulfidation levels and decreased enzyme activity compared with untreated groups. Meanwhile, H<sub>2</sub>S alone failed to affect enzyme activity. GAPDH activity also showed a concentration dependent decrease in response to **301** with a half inhibition concentration of approximately 1 μM (Figure 3E). Maximal inhibition was achieved with 5 μM of the **301** with 17 ± 1% catalytic activity remaining. Further

**Figure 3.** A: Work flow of GAPDH S-persulfidation process; B and C: GAPDH S-persulfidation level assay. GAPDH (2 mg/mL) was subjected to different treatments and analyzed by the protein S-persulfidation switch tag assay; D: GAPDH activity assay; All groups have 10 units/mL PLE and 2% DMSO. (1) 100 μM **301**; (2) 100 μM Na<sub>2</sub>S<sub>2</sub>; (3) 100 μM H<sub>2</sub>O<sub>2</sub> + 100 μM Na<sub>2</sub>S; (4) 200 μM Na<sub>2</sub>S; (5) PLE alone; GAPDH was subjected to various treatment at 37 °C for 0.5 h, then its S-persulfidation level and activity was determined. E: Concentration dependent inhibition of GAPDH activity by **301**. 2 μg/mL GAPDH was incubated with various concentration of **301** at 37 °C for 0.5 h with 10 units/mL PLE, after which the enzyme activity was determined. Then each group was incubated with 2 mM DTT at r.t. for 2 h, after which the GAPDH activity was measured. Values are means ± SEM. n = 3, \*\*P < 0.01.

increase in prodrug concentration to 10 μM did not decrease the enzyme activity further. After treatment with **301**, GAPDH was treated with 2 mM DTT at r.t. for 2 h, which would reduce the S-persulfidation product to free the thiol group again. Indeed, enzyme activity was restored to 75–95% of its original activity by DTT treatment. Considering the important roles of GAPDH,<sup>51,52</sup> the above results suggest an important role for H<sub>2</sub>S<sub>2</sub> in energy metabolism, proliferation and redox balance.

In conclusion, we provide a general strategy to H<sub>2</sub>S<sub>2</sub> prodrugs with well-defined release mechanism. Secondly, controllable release patterns and tunable release rates have been achieved. Such a H<sub>2</sub>S<sub>2</sub> donor can directly induce protein S-persulfidation, leading to significant enzyme activity changes. This novel series of H<sub>2</sub>S<sub>2</sub> prodrugs should be important research tools for future studies.
