Received October 10, 2004; E-mail: tanabe@kwansei.ac.jp

The Claisen condensation is recognized as a fundamental and useful C–C bond-forming reaction in organic syntheses.¹ In general, strong basic reagents (NaOR, LDA, MHMDS, MH, etc.) are used to conduct this reaction. The Ti- (*or* Zr-) *self*-Claisen condensation² possesses powerful reactivity compared with that of the conventional method using strong bases; this method afforded efficient and practical syntheses for *Z*-civetone,³ 1 β -methyl-carbapenem,⁴ and an omuralide analogue.⁵ A related Ti-direct aldol reaction, originally pioneered by Evans' group,⁶ also exhibits powerful reactivity for the crossed addition between different ketones⁷ and is utilized for the efficient syntheses of an anti-Methicillin-resistant *Staphylococcus aureus* carbapenem,⁸ (*R*)-muscone,⁷ and (*R*)-mintlactone.⁹

The major problem of the Claisen condensation lies in the difficulty in directing the reaction; that is, a general crossed condensation between different esters or between esters and acid chlorides, all of which possess α -protons, has not been documented. We disclose here the first general Ti-*crossed*-Claisen condensation between a 1:1 mixture of esters and acid chlorides to provide a variety of β -keto esters (Scheme 1). These functionalized β -keto

Scheme 1

esters served as a fundamental and useful precursor for organic syntheses, especially for chiral synthons utilizing asymmetric transformations such as hydrogenations,¹⁰ metal hydride reductions,¹¹ enzymatic reductions,¹² and asymmetric alkylations at the α -position.¹³

The Ti-*self*-Claisen condensation of simple esters proceeds very rapidly, even at -45 °C, within 0.5 h. Taking this information into account, to realize the Ti-*crossed*-Claisen condensation, we chose acid chlorides as the reactive acceptor electrophile.

As depicted in Table 1, the result of an initial attempted reaction of methyl hexanoate with propanoyl chloride at -45 °C for 0.5 h, however, was disappointing (entry 1). The major product was decomposed propanoic acid (ca. 80%) with undesirable *self*condensed β -keto ester (ca. 30%), and the desired *cross*-condensed β -keto esters were obtained in low yield (15%).

To solve the problem, *N*-methylimidazoles **1** were employed as the key cocatalyst, because acid chlorides condense with *N*methylimidazole to form an activated electrophilic acylammonium intermediate **2**.¹⁴ Screening of some available *N*-methylimidazoles

^{*a*} Isolated. ^{*b*} Determined by ¹H NMR of crude products. ^{*c*} i Pr₂NEt was used instead of Bu₃N. ^{*d*} 1.6 equiv of toluene solvent. ^{*e*} 0–5 °C.

1 revealed promising result with the 2-Et analogue **1c** (80%, cross/ self = 98/2; entry 4). Thus, the reactions of several esters with linear (not branched) acid chlorides proceeded smoothly to give the desired *cross*-products in good yields with excellent selectivities (entries 6, 7, and 9).

For β -branched acid chlorides, 2-Me analogue cocatalyst **1b** matched the reaction with regard to yield and selectivity (cross/ self $\rightarrow >91/9$; entries 10–12). 2-H analogue **1a** was most favorable for β , β -disubstituted or α -branched acid chlorides (entries 13–27).¹⁵

¹ Isolated. ^b Determined by ¹H NMR of the crude product. ^c Using the 2-benzloxy propanoic acid (97% ee), we obtained the desired β -keto ester (93% ee; see ESI).

Various functionalities in both esters and acid chlorides were tolerated during the Ti-crossed-Claisen condensation.

As a notable extension, we investigated the Ti-crossed-Claisen condensation using *carboxylic acids*. We designed a novel protocol utilizing mixed anhydrides 3 generated in situ between sodium carboxylates and Cl₃CC(=O)Cl. (Table 2) (for screening of the acyl chloride co-reagents, see Supporting Information). Thus, the plausible reactive intermediate 4 successfully reacted with methyl hexanoate to give the desired *cross*-condensed β -keto esters with good to excellent yield and selectivity.

Finally, to demonstrate the utility of the present Ti-crossed-Claisen condensation, we performed the efficient short-step syntheses of two natural, representative, and useful perfumes, cisjasmone $(8)^{16}$ and (R)-muscone $(12)^{17}$ (Scheme 2). Synthesis of

^{*a*} Conditions: (a) 1c, TiCl₄-iPr₂NEt, CH₂Cl₂ (61%). (b) 5 M aq KOH, EtOH, then 1 M aq HCl (76%). (c) 1b, TiCl₄-Bu₃N, CH₂Cl₂ (76%). (d) 5 M aq NaOH, MeOH, then 6 M aq HCl (95%). (e) Grubbs catalyst second generation, ClCH₂CH₂Cl, then Pd-C, H₂, AcOEt (74%).

these compounds is a standard model for novel reactions due to their utility and interesting structures.

The Ti-crossed-Claisen condensation of ethyl levulinate (6) with readily available acid chloride **5** proceeded smoothly to give β -keto ester 7. The high chemoselectivity should be noted: the reaction site of **6** was not the α -position of the ketone but that of the ester (see also Table 1, entry 16), and the ketone function did not require the protection.¹⁸ A one-pot hydrolysis-decarboxylation and an aldol condensation afforded cis-jasmone (8) in 46% overall yield.

The Ti-crossed-Claisen condensation between both commercially available methyl 10-undecenate and (R)-citroneric acid afforded β -keto ester 10, which was converted to ketone 11 by hydrolysisdecarboxylation. Second-generation ring-closing metathesis of 11,¹⁷ followed by catalytic hydrogenation, afforded (R)-muscone (12)in 53% overall yield. These two syntheses are regarded as simplest compared with hitherto reported methods.

In conclusion, we developed the Ti-crossed-Claisen condensation between a 1:1 mixture of esters and acid chlorides or carboxylic acids. The present method is a new avenue for the synthesis of a variety of β -keto esters, which will be useful achiral and chiral synthons. As a notable application, we utilized this method for the efficient short syntheses of cis-jasmone and (R)-muscone.
