Tetraarylpyrazoles are synthesized from commercially available materials in three steps and found to exhibit Aggregation Induced Emission Enhancement (AIEE) characteristics. By removing one aryl unit in the tetraarylpyrazole leads to Aggregation Caused Quenching (ACQ), thus, the number of aryl groups plays an important role to explore such phenomena.

Pyrazole is an interesting class of five-membered heterocyclic compound.¹ This motif shows remarkable activities in biological systems² (anti-inflammatory, anti-pyretic, anti-microbial, anti-viral, anti-depressant, agrochemicals etc.), optical sensors³ (cosmetic colourings, optical brighteners, UV stabilizers, photoinduced electron transfer systems), suitable to stabilize various metal ions and effectively utilized as ligands in cross-coupling reactions.⁴ Thus, the research is mainly focused on the synthesis of substituted pyrazole derivatives.⁵ Although several excellent methods are known for the synthesis of substituted pyrazole derivatives in the literature,⁶ developing a new protocol with an interesting property is always needed.²

The development of efficient luminophoric materials is of great interest for both fundamental research and practical applications. The main problem associated with the emission of most luminogenic materials in the solid state is Aggregation Caused Quenching (ACQ) effect which results in unsatisfactory efficiency during film formation, thereby preventing them from real world applications.8 In order to solve this issue, Tang et al and Park et al discovered two novel photoluminescence phenomena such as Aggregation Induced Emission (AIE) and Induced Emission Enhancement respectively.9 Since then, researchers have developed wide range of AIE and AIEE active organic luminophoric materials revealing their applications in thin film display, light emitting technology etc.¹⁰ Among them, 1,1,2,3,4,5-hexaphenylsilole (1) was the first AIE active molecule, which was non-emissive in

Chart 1

Synthesis of tetraarylpyrazoles are scarcely reported. 12,13 These methods suffer low yield, less substrate scope and mult step syntheses of starting materials. Therefore, we envisione 1 a simple synthetic route to prepare the tetraarylpyrazoles \angle from commercially available materials in three steps (Chart 1. The key step of the synthetic route is Suzuki cross-coupling of 4 bromotriarylpyrazoles 3 with arylboronic acids. Thus, Le required 4-bromotriarylpyraozles 3 were synthesized from 3dicarbonyl compounds in two-steps. The first step cyclocondensation of 1,3-diarylpropan-1,3-diketone with ar I hydrazines in refluxing acetic acid and then followed by I bromosuccinimide bromination of the resulting pyrazoles 4 ... CCl₄ (Schemes 1 & 2, ESI†). Next, we focused on the $k\epsilon$ reaction of tetraarylpyrazoles synthesis. Thus, the reaction of 4 bromo-1,3,5-triphenyl-1H-pyrazole (3a, Ar¹ = Ph) wit. phenylboronic acid was carried out under typical Su

dilute solution, however, highly emissive upon aggregation due to its propeller orientation. Pa Our ongoing interest in synthesis of 1,3,4,5-tetraphenyl-1*H*-pyrazole (**2a**, Ar¹ = Ar² = Ph), ll which is closest analogue of **1**, will show AIE or AIEE characteristics. Herein we wish to report the synthesis of tetraarylpyrazole derivatives by simple and efficient synthetic methodology. Further, the AIEE behavior of pyrazole derivatives and the roof aryl groups on the photoluminescence properties ar examined.

reaction conditions. However the expected 1,3,4,5-tetraphenyl-1H-pyrazole (**2a**) was not formed, instead, 1,3,5-triphenyl-1H-pyrazole (**4a**, Ar¹ = Ph) was obtained as major product via debromination. To overcome debromination product, we screened various reaction conditions to optimize Suzuki reaction of 4-bromopyrazole derivative **3a** with phenylboronic acid (Scheme 3, Table 1, ESI†). We found that 1.1 equiv of phenylboronic acid with 5 mol% of Pd(PPh₃)₄ in 1.5 equiv of Cs₂CO₃ in refluxing THF afforded the expected 1,3,4,5-tetraphenyl-1H-pyrazole (**2a**) in 75% yield (Scheme 1).

Scheme 1 Synthesis of tetraarylpyrazoles 2a-2i.

We examined various substituted arylboronic acids under similar reaction conditions. For electron donating group, 4methoxyphenyl and 2-methoxyphenylboronic acids were effectively coupled with 4-bromopyrazole 3a affording 1,3,4-triphenyl-4-(4-methoxyphenyl)-1*H*-pyrazole (2b) and 1,3,4-triphenyl-4-(2-methoxyphenyl)-1H-pyrazole (2c) in good yields (Scheme 1). Whereas electron withdrawing group such as -CHO substituted phenylboronic acid gave very low yields of 2d (37%). Further, we studied electron donating and withdrawing groups effect on 1-N-aryl substituted pyrazole ring. These groups did not influence the yield of the cross-coupled products 2e-2g (Scheme 1). However, 1-N-heteroarylpyrazole required higher catalyst loading (15 mol%) to obtain good yield of coupled product 2i. Successfully, the heteroarylboronic acid was also coupled with 3a affording 4-heteroaryl substituted pyrazole derivative 2h in 75% yield.

The newly synthesized tetraarylpyrazoles are highly soluble in organic solvents, however, insoluble in water. The absorption spectrum of ${\bf 2a}$ in acetonitrile showed a broad band between 250 and 400 nm attributed to the π to π^* transition. In the fluorescence spectrum, the dilute solution of ${\bf 2a}$ exhibits a weak emission band at 370 nm (Fig. S1b, ESI†), when excited at 280 nm with the quantum yield (${\bf 0}_F$) of 0.17. These results are comparable to those of similar pyrazole derivatives. Intriguingly, a dramatic change in fluorescence emission intensity is observed in the water-acetonitrile mixture. Up to 70% of water in acetonitrile/water mixture, the emission band at 370 nm is remained unchanged; however, as the water content

increased from 70% to 90%, the emission intensity at 3.70 minimal enhanced with the quantum yield (Φ_F) of 0.36, which is twoffold higher as compared to 2a in pure acetonitrile solution (Fig. 1a). Apparently, the emission of 2a is boosted by aggregation thereby making it AIEE active. The intensity variation suggest that 2a starts to aggregate as the water fraction reaches 70% and then, the aggregate continues to increase as the water content increases from 70% to 90% (Fig. 1a inset). Overall, when the water content increased to 70%, which reaches the critic I limit, upon further addition of a small amount of water significantly promotes efficient pyrazole aggregation, leading to enhancement in the emission intensity.

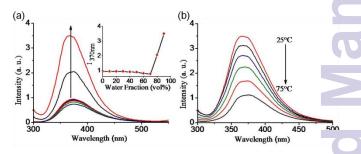

Fig. 1(a) Emission spectra of 2a in acetonitrile/water mixtures with increasing amount of water (f_w =0-90 vol%). Inset shows the changes in the emission intensities of 2a with the water contents in the acetonitrile/water mixture. (b) Temperature effect on the emission intensity of 2a in acetonitrile/water (1:9 v/v), (λ_{ex} =280 nm)

Further, the effect of temperature on the emissic spectrum of **2a** in the solvent mixture (1:9 v/ acetonitrile/water) was also investigated (Fig. 1b). When the temperature was increased from 25 °C to 75 °C, the emissio intensity at 370 nm was decreased gradually. These result suggest that the aggregated state of the compound at lower temperature breaks into monomer like state at highe temperatures. Thus, substantiates the mechanism of restricted intramolecular rotation (IMR) of the aryl groups upon aggregive formation. Overall, the aggregates at the low temperature are more rigid and more emissive than at higher temperature. Similar trend was observed in 2e and 2i (Fig. S5-8 for 2e & S9-1. for 2i, ESI†). The aggregate formation of 2a, 2e and 2i at 90% c acetonitrile/water solvent mixture were further confirmed t dynamic light scattering (DLS) studies, where the particle size were found to be 150 nm, 224 nm and 172 nm, respectively. The nanoparticle size reflects an effective restriction in the IMR of the fluorophore, resulting in enhanced emission. The single crystal X-ray analysis of 2a and 2i further affirmed the restriction in IMR during aggregation.

The single crystal X-ray structure analysis is shown in Fig 2a and 2b. As observed from the spectral analysis, four phenyl **C**, **D** and **E** positions) units are connected with the pyrazole core. The phenyl units are deviated from the mean pyrazole plan with the tilt angle of 49.6° to 52.4° in **2a** and 50.8° to 53.1° in **2** respectively. In order to avoid the steric crowding, the phenyl units are arranged in propeller fashion in the pyrazole core. The π - π interaction plays a major role for Aggregation Caused Quenching (ACQ). 9a However, such interactions in the cryst 1 analyses of **2a** and **2i** are not found, instead, we observe two

Journal Name COMMUNICATION

intermolecular hydrogen bonding interactions such as C-H...N and C-H...Ph(π) interactions. The crystal analysis of **2a** and **2i** generate two 1-D arrays through the intermolecular hydrogen bonding interaction (Fig. S14, 15 & S20, 21, ESI+), where three molecules of pyrazole are involved to generate such arrays and are formed between; (i) pyrazole N (N2), p-CH in the **B**-phenyl unit (C7-H7) of one molecule interacts with p-CH in the E-phenyl unit (C25-H25) of the second molecule and pyrazole N (N2) of third molecule with the distances and angles of C7-H7...N2 and C25-H25...N2 are 2.78 Å, 141° and 2.80 Å, 140° for 2a and the respective values in 2i are 2.66 Å, 133° and 2.70 Å, 145° (Fig. S14 & S18) respectively, and (ii) one of the CHs (C6-H6) in the Dphenyl ring and phenyl π cloud of **B**-ring (Ph- π) of one of the pyrazole unit interacts with phenyl π -cloud of **C**-ring of the second molecule and one of the CHs (C26-H26) in the E-phenyl ring of the third molecule with the distances and angles of C6- $H6...Ph(\pi)$ and C26-H26... $Ph(\pi)$ are 3.00 Å, 144° for **2a** and the respective values in 2i are 3.05 Å, 144° and 2.92 Å, 145° (Fig. S15 & S21) respectively. Combining these two 1-D arrays, 2a (Fig. 2c) and 2i (Fig. S22, ESI†) generate 2-D supramolecular assembly in the solid state. Overall, the phenyl rings present in the pyrazole units are effectively packed in a propeller manner by the intermolecular hydrogen bonding interactions which restrict the intramolecular rotation of such units in the solid state, thus leads to emission enhancement, as observed in the aggregated state.

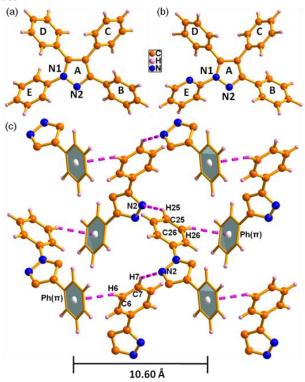

Fig. 2 Single crystal X-ray structure of 2a and 2i. (a & b) Top views of 2a and 2i. (c) 2-D array in 2a. The aryl units which are not involved in the intermolecular hydrogen bonding interactions are omitted for clarity.

Now, the question is, whether all the four phenyl rings are really essential for generating AIEE phenomenon or not. In order to justify this, we further extended similar such experiments with 1,3,5-triphenyl-1H-pyrazole (4a). The 15 μ M

acetonitrile solution of 4a showed an absorption band at nm, when excited at this wavelength, WHICH 3016 P16 VED 73. emission band at 360 nm. The similar experiments were performed by increasing the water fraction from 10% to 90% imthe acetonitrile solution of 4a (Fig. 3a). Instead of emissic enhancement, we observed the Aggregation Caused Quenching (ACQ) effect. The photoluminescence quantum yield (Φ_F) of 4 1 in acetonitrile is found to be 0.35, which is decreased as compared to **4a** in acetonitrile/water mixture and the \mathcal{O}_F value is 0.31. This is further confirmed by single crystal X-ray structure and analysis (Fig. 3b & 3c). The phenyl units are deviated from the mean pyrazole plane with the tilt angle of 33.6° (B), 29.5 (C) and 64.1° (D), respectively, which clearly reflects that phen. units are not arranged in propeller format (Fig. 3a). In additio the crystal analysis of 4a revealed two 1-D arrays (Fig. S27 S28, ESI†). One of the arrays is between **B**-phenyl unit (C4-H₄) and **C**-phenyl unit (π -cloud) of two molecules (Fig. S27, ESI[†]) the second array is between D-phenyl unit (C10-H10) of one molecule with the **C**-phenyl unit (π -cloud) of neighbo molecule with the distances and angles of C4-H4...Ph(π) and C10-H10...Ph(π) are 2.88 Å, 147° and 2.88 Å, 156°, (Fig. 2-) respectively. The decrease in emission intensity upc aggregation is attributed to the intermolecular π - π stacking interaction in 4a (Fig. S29, ESI †). The π - π distance between two closely packed molecules is 5.87 Å; however such distance in the case of 2a and 2i are 10.60 Å and 10.54 Å respectively (Fig. 2c and Fig. S24, ESI†). We also studied 1,3,4-triphenyl-1/ pyrazole^{11a} and observed similar trend as in **4a** (Fig. S31, ESI†).

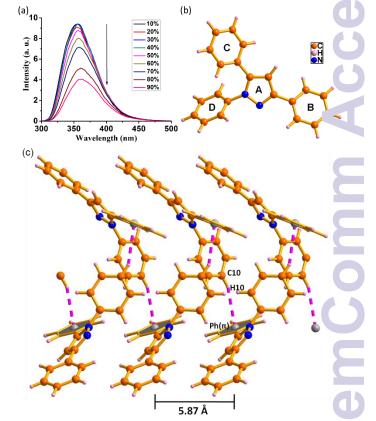

Fig. 3 (a) Emission spectra of **4a** with increasing addition of water in acetonitrile (f_w =0-90 vol%). (b) Single crystal X-ray structure of **4a**. (c) 1-1 array in **4a**.

COMMUNICATION Journal Name

In conclusion, we have synthesized a library of tetraarylpyrazoles from commercially available starting materials by a simple and straightforward synthetic protocol. By using tetraarylpyrazoles, we have exploited the AIEE phenomenon which is hitherto unknown in the literature. We also explored that four phenyl rings were essential to demonstrate AIEE phenomenon, reduction in one of the phenyl units led to ACQ.
