Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

Supporting Information

ABSTRACT: Cloaking its carboxyl groups with a hydrophobic moiety is shown to enable a protein to enter the cytosol of a mammalian cell. Diazo compounds derived from (*p*-methylphenyl)glycine were screened for the ability to esterify the green fluorescent protein (GFP) in an aqueous environment. Esterification of GFP with 2-diazo-2-(*p*-methylphenyl)-*N*,*N*-dimethylacetamide was efficient. The esterified protein entered the cytosol by traversing the plasma membrane directly, like a smallmolecule prodrug. As with prodrugs, the nascent esters are substrates for endogenous esterases, which regenerate native protein. Thus, esterification could provide a general means to deliver native proteins to the cytosol.

Approximately 20% of the drugs in today's pharmacopeia are proteins.¹ Essentially all of those proteins act on extracellular targets. This limitation arises from an intrinsic inability of proteins to enter the cytosol.² Although viral vectors can be used to deliver DNA that encodes a protein of interest, this genetic approach lacks regulation and can induce stress responses, carcinogenesis, or immunogenicity.³ In contrast, the direct delivery of proteins into cells would enable temporal control over cellular exposure and minimize deleterious off-target effects.⁴

Proteins can be delivered into cells by using sitedirected mutagenesis,⁵ irreversible chemical modification,⁶ conjugation of transduction domains (such as cellpenetrating peptides, CPPs),⁷ cationic lipid carriers,⁸ or electroporation.⁹ Many of these strategies show promise but also pose problems,^{2,4} such as inefficient escape from endosomes or inapplicability in an animal.

To cross the plasma membrane, proteins must overcome two barriers: Coulombic repulsion from the anionic glycocalyx and exclusion from the hydrophobic environment of the lipid bilayer.¹⁰ Natural and synthetic systems suggest means to overcome these barriers. For example, mammalian ribonucleases are capable of cytosolic entry that is mediated by clusters of positively charged residues.¹¹ Cellular uptake can also be enhanced by exogenous hydrophobic moieties.¹² For example, noncovalent complexation with pyrene butyrate enables the cytosolic delivery of a green fluorescent protein (GFP) conjugate to a cationic CPP.¹³ Additionally, several natural and synthetic protein transduction domains (*e.g.*, penetratin, TP10, and *p*VEC) consist of cationic and hydrophobic residues, which impart an amphipathic character.^{7e,7f,14} Their hydrophobic residues are crucial for mediating membrane translocation.

We envisioned a different strategy—one that invokes a chemoselective reaction that remodels the protein surface to become less anionic and more hydrophobic. The surface of proteins displays cationic groups (*i.e.*, guanidinium, ammonium, and imidazolium) and anionic groups (carboxylates). We hypothesized that the

Figure 1. Bar graph showing the extent of esterification of the superfolder variant of GFP with diazo compounds 1-6 (black) and the internalization of the ensuing esterified GFPs into CHO-K1 cells (green). Values (\pm SD) were determined by mass spectrometry and flow cytometry, respectively. Parenthetical log*P* values were calculated with software from Molinspiration (Slovensky Grab, Slovak Republic).

esterification of its carboxyl groups could endow a protein with the ability to access the cytosol. In particular, by cloaking negative charges with a hydrophobic moiety, we might increase the nonpolar surface area while enabling endogenous positive charges to manifest favorable Coulombic interactions with anionic cell-surface components. The ensuing mode-of-action would resemble that of small-molecule prodrugs, which have been in the pharmacopoeia for decades.¹⁵

To effect our strategy, we employed diazo compounds derived from (*p*-methylphenyl)glycine. We had shown previously that the basicity of such diazo compounds enables the efficient esterification of carboxylic acids in an aqueous environment.¹⁶ Now, we exploited the modular nature of this scaffold. Specifically, we deimidogenated azide precursors^{16,17} to access diazo compounds **1–6**, which span a range of hydrophobicity (Figure 1).

Then, we screened solution conditions for maximal protein esterification by our scaffold. We were aware that the mechanism of esterification requires a protonated carboxyl group,¹⁸ which is encouraged by a low pH and an organic cosolvent. Using GFP and diazo compound **3**, we found that an aqueous solution at pH 6.5 that contains 20% v/v acetonitrile gives a high yield of esters (Figure S1). These conditions should be tolerable by most proteins.

Next, we evaluated diazo compounds 1-6 for their ability to esterify a protein and facilitate its internalization into a mammalian cell. We found that more polar diazo compounds alkylated more carboxyl groups than did less polar compounds (Figures 1 and S2). Then, we treated live cells with esterified proteins and quantified internalization with flow cytometry. We discovered that the level of cellular internalization parallels the number of labels per protein (Figure 1), which suggests that

Figure 3. Images of the nuclear internalization of a protein that contains a nuclear localization signal and its esterified variant. CHO-K1 cells were incubated with nlsGFP or nlsGFP–1 (15 μ M) for 2 h at 37 °C. Cells were then washed, stained with Hoechst 33342 and WGA–Alexa Fluor 647, and imaged by confocal microscopy (Hoechst 33342: ex. 405 nm, em. 450 nm; WGA–Alexa Fluor 647: ex. 647 nm, em. 700 nm; GFP: ex. 488 nm, em. 525 nm). Scale bars: 25 μ m.

simply masking anionic groups is advantageous. Moreover, cellular fluorescence increases in a time-dependent manner (Figure S3), as expected for a process based on vectorial diffusion from the outside to the inside.

Of the six diazo compounds, compound 1 was the most effective in engendering cellular uptake and was selected for further study. On average, 11 of the 32 carboxyl groups in GFP were masked as neutral esters by diazo compound 1 (Figure S2). Although the esterification of 11 carboxyl groups in GFP could produce ${}_{32}C_{11} =$ 1.2×10^8 different molecules, esters are most likely to form with solvent-accessible carboxyl groups that have a high pK_a value (Table S1).¹⁸ That trend was apparent in tandem mass spectrometry data (Figure S4). This selectivity has fortuitous consequences. An aspartate or glutamate residue within a hydrophobic patch is a likely target for esterification, which would extend the size of the patch. Clustered anionic residues likewise have high pK_a values, and their esterification would overcome a strong deterrent to cellular uptake. In contrast, an aspartate or glutamate residue within a salt bridge is unlikely to be esterified, but a salt bridge manifests less Coulombic repulsion with anionic cell-surface components than do isolated or clustered anionic residues.

We used confocal microscopy to visualize the uptake of GFP by live mammalian cells. For calibration, we compared the uptake of GFP with that of a "supercharged" variant in which site-directed mutagenesis was used to replace anionic residues with arginine (Figure S5).^{5a} Unmodified GFP did not enter cells (Figure 2). Super-charged GFP did enter cells, but produced a punctate pattern of fluorescence that is suggestive of endosomal localization. At 4 °C, which is a temperature that precludes endocytosis,¹⁹ the fluorescence from supercharged GFP was scant and localized to the plasma membrane.

Images of cells treated with GFP-1 were in marked contrast to those treated with unmodified GFP or super-

charged GFP. At 37 °C, treatment with GFP–1 elicited diffuse fluorescence, suggestive of cytosolic localization (Figure 2). Most remarkably, this pattern persisted at 4 °C, indicating that uptake does not rely on endocytosis. In other words, GFP–1 appears to enter cells by passing directly through the plasma membrane, like a small-molecule prodrug.¹⁵

To enter the nucleus, a protein must pass through the cytosol. To verify cytosolic entry, we reiterated a known GFP variant bearing a nuclear localization signal $(nlsGFP; Figure S5)^{20}$ and esterified that variant with compound 1 (Figure S6). We then treated live cells with either nlsGFP or esterified nlsGFP (nlsGFP-1) and visualized the cells with confocal microscopy. In the ensuing images (Figure 3), nlsGFP colocalizes with membrane stain (Pearson's r = 0.21) and is excluded from the nucleus (r = -0.12). This result is expected, as GFP is impermeant but a nuclear localization signal is cationic and can form salt bridges with the anionic glycocalyx. In contrast, nlsGFP-1 not only exhibits diffuse staining like GFP-1 (Figure 2), but also colocalizes with a nuclear stain (r = 0.51) to an extent expected for this particular variant.²⁰ These data indicate that nlsGFP-1 accesses the nucleus and, thus, the cytosol.

Finally, we investigated the bioreversibility of esterification. Incubation of a model protein esterified with diazo compound **1** in a mammalian cell extract resulted in the complete removal of labels (Figure S7). This finding is consistent with an inability of de-esterified GFP–**1** (*i.e.*, GFP) to escape from the cytosol and thus accumulating there (Figure S3). Thus, the esters formed upon reaction with **1** are substrates for endogenous esterases, like prodrugs.¹⁵ Moreover, the alcohol product of the esterase-mediated hydrolysis is benign to mammalian cells (Figure S8).

In summary, we have demonstrated that esterification of protein carboxyl groups with a tuned diazo compound can engender delivery of the protein across the plasma membrane as if it were a small molecule. Further, this chemical modification is traceless, being removable by cellular esterases. This delivery strategy provides an unprecedented means to deliver native proteins into cells for applications in the laboratory and, potentially, the clinic.
