Aromatic compounds in trifluoroacetic acid were readily carboxylated with CO in the presence of a catalytic amount of palladium(II) acetate under mild conditions to give aromatic carboxylic acids in good yields.

In previous papers, we reported direct carboxylation of aromatic compounds with CO or CO₂ by palladium catalysts.¹ However, the reaction requires severe reaction conditions such as high CO pressure and temperatures. In the course of a survey of the synthetic reactions *via* the transition metal catalyzed C-H bond activation, we found that the Pd(OAc)₂/K₂S₂O₈/trifluoroacetic acid (TFA) system² caused the direct carboxylation of arenes under very mild reaction conditions. We now wish to report the details of the reaction as depicted in eq. 1.

First, we examined the carboxylation reaction of benzene to give benzoic acid (**1**) using benzene (5 mL, 56 mmol) and CO (1 atm) in the presence of Pd(OAc)₂ (0.5 mmol), and an oxidizing agent in TFA (5 mL) at room temperature for 20 h. These results are listed in Table 1. In the absence of an oxidizing agent, reaction gave **1** in 23% yield, and palladium black precipitated as the reaction proceeded (entry 1 in Table 1). Addition of Cu(OAc)₂ increased the yield of **1** although the reaction did not

proceed catalytically (entries 1 and 2 in Table 1). In order to make the reaction catalytic with respect to palladium(II), several oxidizing agents of Pd(0) to Pd(II) were tested. Of the oxidizing

agents, K₂S₂O₈ in TFA was found to give the best result (entry 4 in Table 1). In the Pd(II)/K₂S₂O₈ catalytic system, the addition of Cu(OAc)₂ decreased the yield of **1** in contrast to the reactions without K₂S₂O₈.

Then, the effect of the amount of Pd(OAc)₂ on the yield of **1** under similar reaction conditions was investigated. These results are shown in Figure 1. As is apparent from Figure 1, the

Figure 1. Relationship of [Pd(OAc)₂] vs. yield of **1**.

yields of **1** increased with decreasing amounts of Pd(OAc)₂. It seems that the yield of the carboxylation of benzene does not depend on the amounts of K₂S₂O₈ but does on the amount of Pd(OAc)₂.

The representative results for the palladium(II)-catalyzed carboxylation of various aromatic compounds under normal CO pressure and at room temperature are summarized in Table 2. Various aromatics are converted to the corresponding aromatic carboxylic acids in good yields under mild conditions (entries 6-9 in Table 2). Entries 1-5 in Table 2 indicate the time course of the carboxylation of benzene. The yield of **1** increased monotonously, and after 120 h the yield became almost constant. Toluene, anisole, and chlorobenzene gave the corresponding acids with *ortho*-*para* orientation, and naphthalene afforded α - and β -naphthoic acids in a 66:34 ratio.

The typical preparation of **1** is as follows (entry 5 in Table 2): a solution of Pd(OAc)₂ (22.5 mg, 0.1 mmol), benzene (5 mL, 56 mmol) and K₂S₂O₈ (1.352 g, 5 mmol) in TFA (5 mL) was placed in a 50 mL round-bottomed flask equipped with a balloon filled with CO. The mixture was stirred at room temperature for 120 h. Usual work-up gave **1** (397 mg) in 3300% yield based on Pd.

That the reaction proceeds with *ortho*-*para* orientation when an electron-releasing group is attached to the benzene ring and that naphthalene gives α -naphthoic acid as a main product suggest that the reaction proceeds *via* electrophilic attack of cationic palladium(II).³ Competitive reaction of benzene and chlorobenzene with CO gave benzoic and chlorobenzoic acids in 580 and 60% yields, respectively. The relative reactivity was found to be in the order of anisole > toluene > benzene > chloro-

Table 2. Pd(OAc)₂ Catalyzed Direct Carboxylation of Arenes^a

Entry	Substrate	Time (h)	Product	Yield ^b
1	Benzene	5	Benzoic acid (1)	600
2	"	10	"	800
3	"	20	"	1400
4	"	40	"	2200
5	"	120	"	3300
6	Toluene	20	Toluic acids	800 ^c (26:6:67) ^d
7	Chlorobenzene	20	Chlorobenzoic acids	1700 (19:27:54) ^e
8	Anisole	20	Anisic acids	1200 ^c (33:0:67) ^d

benzene by competitive reactions. This result also indicates that the reaction is electrophilic.

In order to increase the conversion of benzene for the synthesis of **1**, the effect of the amounts of benzene, K₂S₂O₈, and TFA was tested. These results are listed in Table 3. One

can see that the yield of **1** increases with decreasing amounts of benzene and TFA. The datum of entry 5 in the table shows that the carboxylation of benzene proceeds quantitatively when 1 mmol of benzene, 2.5 mmol of K₂S₂O₈, and 1 mL of TFA were employed in the presence of 10 mol% of Pd(OAc)₂ catalyst. Under those optimum conditions, the carboxylations of chlorobenzene, toluene and anisole proceeded to afford the corresponding acids in 100, 67, and 60% yields based on substrate, respectively.

Table 3. Effect of the Amounts of Benzene, K₂S₂O₈, and TFA^a

Entry	Benzene (mmol)	K ₂ S ₂ O ₈ (mmol)	TFA (mL)	Yield of 1 (%) ^b
1	56	5	5	2.5 (1400)
2	10	5	5	17 (1700)
3	1	2.5	5	48 (480)
4	1	2.5	2.5	89 (890)
5	1	2.5	1	100 (1000)

^aPd(OAc)₂ (0.1 mmol), CO (1 atm, balloon), r.t. ^bIsolated yields based on benzene and the numbers in parentheses are the yields based on Pd.

Isotope effect for this carboxylation process was examined by using *d*₆-benzene. The competitive reaction of C₆H₆ and C₆D₆ with CO afforded the mixture of **1** and *d*₅-**1**. The *k_H/k_D* ratio was found to be 6.1 by GC-MS analysis of the products. This result indicates that the rate-determining step of this reaction is the C-H bond activation of arenes.

Possible reaction mechanism is shown in Scheme 1. Electrophilic attack of an electropositive Pd⁺(OCOCCF₃) species on the benzene ring gives an arylpalladium species, which undergoes insertion of CO to give an aroylpalladium(II). The subsequent reductive elimination gives palladium(0) and the acid anhydride which react with TFA to give ArCOOH and (CF₃CO)₂O. Palladium(0) is reoxidized by K₂S₂O₈ to Pd(II). The reason why the present reaction proceeds under the milder conditions than those of the usual Pd(OAc)₂/AcOH system¹, could be attributed to the formation of more electropositive Pd⁺(OCOCCF₃) as compared with Pd⁺(OCOCH₃) which is formed under the usual conditions.
