Heterobimetallic iron-palladium alkoxysilyl- and siloxyl-complexes catalyse the dehydrogenative tin-tin coupling reaction; high turnover numbers are obtained, whereas modifications of the silicon-containing ligand strongly influence the efficiency of the catalyst.

We have recently reported the synthesis of $[(OC)_3-Fe\{\mu-Si(OMe)_2(QMe)\}(\mu-dppm)Pd(SnPh_3)]$ 2a from

 $(OC)_3\{(MeO)_3Si\}\dot{F}e(\mu\text{-dppm})\dot{P}d(\eta^3\text{-allyl})\}$ **1a** and HSnPh₃. Interestingly, propene elimination was accompanied by evolution of H₂ and formation of Sn₂Ph₆ (ca. 10%) (Scheme 1). We now report that heterobimetallic Fe–Pd siloxyl complexes are efficient catalysts for the dehydrogenative coupling of stannanes. The kinetics of the reaction and the catalytic activity are very sensitive to the nature of the silyl ligand.

Hexaorganoditin derivatives have a wide range of applications and are usually prepared by various organic methods.² Surprisingly, the dehydrogenative coupling of HSnR₃ has received little attention.³ Only a few examples where this reaction is catalysed by organometallic complexes have been reported: [PdCl₂(MeCN)₂], [Pd(Ph)I(PPh₃)₂],⁴ and [Ph₃PCuH]₆⁵ have been used but low catalytic activities were observed. The oligomerisation of H₂SnBu₂ in the presence of metallocene derivatives of Ti and Zr has also been described.⁶

In an attempt to prepare the bimetallic siloxyl complex $(OC)_3Fe\{\mu\text{-SiMe}(OSiMe_3)(QSiMe_3)\}\{\mu\text{-dppm})Pd(SnPh_3)\}$ **2b** by treating HSnPh₃ (two to threefold excess) with a toluene solution of $[(OC)_3\{(Me_3SiO)_2MeSi\}Fe(\mu\text{-dppm})Pd(allyl)]$ **1b**, we noted a vigorous gas evolution with an immediate change from yellow to orange–red. ¹H and ³¹P{¹H} NMR monitoring of the reaction (in [2H_8]-toluene) only showed resonances due to **1b**, whereas Sn_2Ph_6 precipitated (Scheme 1). Further addition of a 10 to 15-fold excess of HSnPh₃ only led to the formation of more Sn_2Ph_6 . A decrease in the intensity of the $^{31}P\{^1H\}NMR$ resonances of **1b** was observed (Ph₃P=O int. ref.) and no other product was evidenced. These observations indicate that **1b** is a catalyst (precursor) for the dehydrogenative tin–tin bond formation.

Increasing the ratio [HSnPh₃]/[1b] and keeping all other parameters unchanged† gave the turnover numbers (TON) reported in Table 1. In run 1, the TON found (490) already indicated a good catalytic activity. Addition of more HSnPh₃ to the final reaction mixture did not yield more Sn₂Ph₆ or H₂ and NMR and IR measurements showed the disappearance of 1b. Owing to the high conversion (91%), we suspected that the catalysis did not proceed further because of the lack of substrate. Indeed, increasing the ratio [HSnPh₃]/[1b] led to a parallel rise of the TON (runs 2–6). Similar TON were obtained for runs 6–8, indicating that the maximum catalytic activity of 1b in Et₂O had been reached (*ca.* 1560 TON).

Scheme 1

Under the conditions of run 6, the volume of H_2 released has been measured (TON νs . time is shown in Fig. 1). After ca. 1 h, a plateau was reached, which corresponds to the maximum catalytic activity of 1b found above. A short induction period was noticed (see inset). The reaction rate rapidly increased and reached a maximum after 10-15 s, the turnover frequency being $> 180\,000~h^{-1}$. It then decreases, presumably because of the relatively short lifetime of the catalyst. Identical kinetic data were obtained with larger quantities of HSnPh₃, thus showing no influence of the substrate concentration.

We reinvestigated the reaction between 1a and HSnPh₃¹ in order to examine the difference in reactivity between 1a and 1b under similar reaction conditions‡ and therefore the influence of the alkoxysilyl group. When HSnPh₃ was added to an Et₂O solution of 1a an immediate change from yellow to red was observed accompanied by a mild evolution of H₂. After three days, the solution was pale yellow and a precipitate of Sn₂Ph₆

Table 1 Catalytic activity of 1b for the synthesis of Sn₂Ph₆ from HSnPh₃ in Et₂O

Runa	Mol ratio [HSnPh ₃]/[1b]	Turnover number $(\Delta)^b$	Conversion rate (%) ^c
1	1070	490 (30)	91
2	1275	600 (25)	94
3	1530	720 (40)	94
4	1710	815 (35)	95
5	3560	1350 (20)	76
6	5180	1560 (30)	60
7	6475	1560 (35)	48
8	7770	1560 (25)	40

^a Data refer to the average values determined for 3–5 experiments/run; for the reaction conditions see footnotes; ^b n Sn₂Ph₆ formed/n catalyst. Δ = difference between highest and lowest values given in parentheses; ^c n HSnPh₃ consumed/n HSnPh₃ initially added.

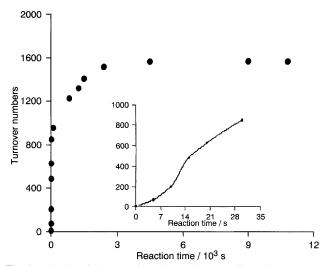

Fig. 1 Evolution of the catalytic activity of 1b in the formation of $\mathrm{Sn_2Ph_6}$ from $\mathrm{HSnPh_3}$, inset represents an expansion of the plot in the first 30 s of the reaction

was formed (0.500 g, TON: 650), whereas ³¹P{¹H} NMR or IR measurements gave no evidence for 1a or 2a. These data indicate that 1a also catalyses the formation of Sn₂Ph₆, but much more slowly and less effectively than 1b. Monitoring the formation of Sn₂Ph₆§ gave the plot shown in Fig. 2 (0). The general aspect of the curve is similar to that obtained with 1b (\bullet). The maximum turnover frequency is 80 h⁻¹ (between 1 and 4.5 h). The plateau is only reached after more than 48 h (cf. 1 h for **1b**).

The change from yellow to red described above being characteristic of the formation of 2, the latter was used instead of 1a: a comparable catalytic activity was observed, indicating that 2 is certainly an intermediate in the catalytic process. Rapid formation of a catalytically active trimetallic Fe-Pd-Sn complex 2b is strongly suggested by the similar colour change observed with 1b, although the former could not be isolated owing to its high reactivity under the reaction conditions of the catalysis.

We suggest that the considerable difference of reactivity between 1a and 1b is related to the nature of the μ_2 - η^2 -SiO bridge.³ This interaction is more stabilizing in 2a than in 2b, and therefore decreases the reactivity of the complex (by masking more effectively the coordination site on the palladium atom required for the catalysis to proceed). The O-donor capacity of the siloxyl ligand is reduced compared with that of an alkoxysilyl ligand owing to the more electropositive character of the Si atom in the former.⁷ A possible mechanism would involve the hemilability of the bridging μ_2 - η^2 -SiO ligand, and

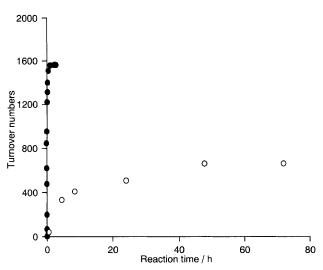

Fig. 2 Comparison between the catalytic activities of 1a (0) and 1b (•)

J. CHEM. SOC., CHEM. COMMUN., 1995

proceed via the alternate opening and closing of the Fe-Si-O-Pd four-membered ring and the transient formation of PdIV species.8 Although the elementary transformations during catalysis would take place at the palladium centre,¶ the function of the iron fragment is to provide the appropriate coordination environment through metal-metal bonding and the Si-containing ligand.

We are grateful to the Centre National de la Recherche Scientifique for support and to Dr M. Knorr for numerous discussions.

Footnotes

† In a typical experiment, a large excess of HSnPh3 was added at 25 °C to an Et₂O (15 ml) solution of 1b. The mixture was stirred for 1 h after which time no more evolution of H₂ was observed. Most of the Sn₂Ph₆ (>90%) was collected by filtration and dried under reduced pressure. The filtrate was evaporated to dryness and the residue washed with 2 × 3 ml of cold Et₂O $(-10 \, ^{\circ}\text{C})$, thus allowing the recovery of the remaining Sn_2Ph_6 (<10%); mp > 225 °C.

‡ Reaction conditions for which the optimum catalytic activity of 1b had been obtained.

§ A set of 18 experiments was started at $t = t_0$ using standard solutions of 1a (8.8 mg, 1.1 10^{-6} mol) and a large excess of $HSnPh_3$ (5000 equiv.) in 15 ml of Et_2O . At t = 1, 4.5, 8.5, 24, 48 and 72 h, three reactions were stopped and the Sn₂Ph₆ formed isolated and weighed. The average TONs were used for the plot.
