(14.III.88)

#### Abstract

A variety of mono- and bis $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-diene $\left.)\right]$ complexes with alkyl, $\mathrm{CH}_{2} \mathrm{OH}, \mathrm{CHO}, \mathrm{COCH} 3, \mathrm{COOR}$, and CN substituents on the 1,3 -diene system have been synthesized. Dienes with a $(Z)$-configurated terminal Me group show steric inhibition of metal complexation resulting in lower yields and formation of tetracarbonyl( $\eta^{2}$-diene) and tricarbonyl( $\eta^{4}$-heterodiene) complexes as additional products. Regioselective attack by C -nucleophiles at the carbonyl C -atom of the functional group with or without concomitant 1,3 migration of the $\mathrm{Fe}(\mathrm{CO})_{3}$ group was used to synthesize polyenes and isoprenoid building blocks as mono- or dinuclear $\mathrm{Fe}(\mathrm{CO})_{3}$ complexes. Wittig-Horner-type reactions of $\mathrm{Fe}(\mathrm{CO})_{3}$-complexed synthons result in stereospecific formation of $(E)$-configurated olefins. The ${ }^{1} \mathrm{H}$-, ${ }^{13} \mathrm{C}$-, and ${ }^{57} \mathrm{Fe}$-NMR spectra of 73 olefinic and allylic organoiron complexes are reported. $\mathrm{H}, \mathrm{H}$, $\mathrm{C}, \mathrm{H}$, and C,C coupling constants have been evaluated and are analyzed in terms of the geometry of the coordinated diene. The results are corroborated by the crystal structure of tricarbonyl[3-6- $\eta-((E)-6$-methyl-3,5-heptadiene-2one)]iron (34) which shows an unusual distortion of the $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=$ group. The ${ }^{57} \mathrm{Fe}-\mathrm{NMR}$ chemical shifts extend over the ranges of $0-600 \mathrm{ppm}$ for $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-diene $\left.)\right]$ complexes, $780-1710 \mathrm{ppm}$ for $\left[\mathrm{Fe}(\mathrm{CO})_{4}\left(\eta^{3}\right.\right.$-allyl $\left.)\right]\left[\mathrm{BF} \mathrm{B}_{4}\right]$ and $\left[\mathrm{FeX}(\mathrm{CO})_{3}\left(\eta^{3}\right.\right.$-allyl) $]$ complexes, and $1270-1690 \mathrm{ppm}$ for $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-enone $\left.)\right]$ complexes, relative to $\mathrm{Fe}(\mathrm{CO})_{5}$.

1. Introduction. - Coordination of 1,3 -dienes to a $\mathrm{Fe}(\mathrm{CO})_{3}$ group provides a means of moderating the reactivity of the unsaturated system to catalytic hydrogenation, hydroboration, and electrophilic and Diels-Alder reactions [2]. It also influences the reactivity of functional groups attached to the diene system in terms of chemo- and stereoselectivity [3]. Furthermore, steric interactions of the $\mathrm{Fe}(\mathrm{CO})_{3}$ group with the diene substituents provide a source for considerable geometric distortions of the diene system as shown by X-ray crystallography [3d] [4] and NMR spectroscopy [5].

A general use of tricarbonyliron-complexed synthons in organic synthesis requires a more than qualitative understanding of these effects, and for this reason, we have synthesized several series of substituted-diene complexes and investigated their structural properties and chemical reactivity. Similar studies have already been reported for $\left[\mathrm{Rh}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$ (diene)], $\left[\mathrm{Co}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)(\right.$ diene $\left.)\right]$, and $[\mathrm{Co}$ (indenyl)(diene)] complexes with 1,3- and 1,4-dienes and have revealed a decreased shielding of the ${ }^{103} \mathrm{Rh}$ - and ${ }^{59} \mathrm{Co}$-NMR resonances with increasing ring size or distortion of the complexed diene ligand [6]. This in turn correlates with a decrease in thermal stability and an increase in catalytic activity in the case of the cobalt complexes [6a] [7]. Therefore, the NMR spectroscopic properties of

[^0]transition-metal diene complexes provide a sensitive probe into the structure and reactivity of such compounds.
2. Synthetic Methods. - 2.1. Functionalized Butadiene Complexes. A variety of methods for the preparation of ironcarbonyl complexes of dienes are described in the literature. Many of these are restricted to special substrates, e.g. metal-vapour synthesis [8], rearrangement of ligands [9], reaction of ironcarbonyls with halogen compounds [10], or ligand exchange reactions [2] [11]. The most convenient way for the synthesis of $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] complexes is the interaction of the ligand with either $\mathrm{Fe}(\mathrm{CO})_{5}$ or $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ from which carbonyl ligands are displaced on heating or irradiation [12].

The $\mathrm{Fe}(\mathrm{CO})_{5} / \mathrm{UV}$ method is especially useful for preparing $\left[\mathrm{Fe}(\mathrm{CO})_{3}(\right.$ diene $\left.)\right]$ complexes of dienes without substituents containing hetero atoms (yields usually $65-85 \%$ ). However, isomerizations and side reactions occurred, with ligands containing a carbonyl function. In this case, the use of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ at elevated temperature provided better results, although yields were somewhat lower ( $45-80 \%$ ). In some cases, this limitation was overcome by the addition of an excess of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ after $c a$. half of the reaction time (cf. Exper.4, Exper. Part). The heterodiene complexes 64 66, 69, and 70 were synthesized by the $\mathrm{Fe}(\mathrm{CO})_{s} / h v$ method (cf. Exper. 5 , Exper. Part) in $60-80 \%$ yield.

The yield of the complexation reaction appeared to be mainly controlled by two effects, electron density and steric hindrances in the s-cis-1,3-diene ligand. Dienes with a terminal substituent with a ( $Z$ )-arrangement relative to the central $\mathrm{C}-\mathrm{C}$ bond have to undergo considerable conformational rearrangement on complexation (see below). On the other hand, a CN group attached to the diene dramatically reduces the reactivity of the ligand, even if no steric strain is present. As a general rule, yields decrease as the $(-M)$-effect of the substituent increases.

In some cases, the tendency to avoid steric strain on complexation resulted in the formation of unexpected products. Thus, the complexation of ( $E$ )-6-methyl-3,5-hepta-dien-2-one is presumably hindered by the interference of the $\mathrm{CH}_{3}(8)$ group with the

Scheme 2

$\mathrm{Fe}(\mathrm{CO})_{3}$ moiety: in addition to 34, a considerable amount of the unstable dark-red enone complex 35 was formed (identification by NMR spectroscopy ${ }^{2}$ ), Scheme 1).

In the synthesis of 37 , the same type of steric interaction led to a $\left[\mathrm{Fe}(\mathrm{CO})_{4}\left(\eta^{2}\right.\right.$-diene $\left.)\right]$ complex 36 as the major product ${ }^{3}$ ) (Scheme 2). This is in accordance with the proposed mechanism for the formation of $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-diene $\left.)\right]$ complexes via the $\eta^{2}$-stage [13].
2.2. Isoprenoid Complexes. 2.2.1. Reactions of Isoprenoid Synthons. It has been shown that aldol condensations and similar reactions of functionalized $\left[\mathrm{Fe}(\mathrm{CO})_{3}(\right.$ diene $\left.)\right]$ complexes can be used for the synthesis of polyene chains [3a]. One of the aims of the present

Scheme 3

repetition

46

52
53

[^1]investigation was the adaptation of this method to the formation of polyisoprene units. The reaction sequence necessary for the achievement of this goal is shown in Scheme 3.

For several reasons, 34 was chosen as starting material: its ligand can be prepared easily from commercially available compounds, and $\mathbf{3 4}$ is stable to air and can be handled without excessive precautions ${ }^{4}$ ).

The action of BuLi and MeCN on 34 at low temperature gave 49 in quantitative yield whereas the corresponding reaction using the 2,4 -hexadienal complex 40 as starting material is described to provide $90 \%$ of the nitrile 47 (cf. Scheme 4) [3a]. The improved yield in the former case is probably due to the migration of the $\mathrm{Fe}(\mathrm{CO})_{3}$ group from a sterically crowded $3-6-\eta$ coordination in 34 to a sterically relaxed $2-5-\eta$ coordination in 49. The reduction $\mathbf{4 9} \rightarrow \mathbf{4 6}$ proceeded as expected using diisobutylaluminum hydride (DIBAH).

Condensation of the aldehyde 46 with the enolate ion of acetone would provide the acetylated terpenoid complex which in turn could have been used as starting material for a repetition of the whole sequence (Scheme 3). For the deprotonation of acetone, $\mathrm{Ph}_{3} \mathrm{CK}$ was used because of its low tendency to attack $\mathrm{C}=\mathrm{O}$ bonds and its deep red colour which allows titration of the substrate. However, on reaction with 46, no migration of the $\mathrm{Fe}(\mathrm{CO})_{3}$, residue to the newly formed double bond occurred, but complex 51 was formed in poor yield. Some modifications including variation of the stoichiometry and inverse addition of the reagent (cf. Exper. Part) led to slightly increased yields of 51, but again no $3-6-\eta$-bonded product could be isolated. The same substrate 46 was subjected to condensation with $\mathrm{MeCN} / \mathrm{BuLi}$ in order to verify that the unusual behaviour of 46 with respect to nucleophilic attack is not a consequence of the applied base. As in the formation of 51, no migration could be observed and a mixture of the corresponding nitriles 52 and $\mathbf{5 3}$ was isolated in high yields. On the other hand, treatment of the 2,4-hexadienal complex 40 with the system $\mathrm{CH}_{3} \mathrm{CHO} / \mathrm{Ph}_{3} \mathrm{CK}$ provided $50 \%$ of $\left[\mathrm{Fe}(\mathrm{CO})_{3}(2-5-\eta-(2,4,6\right.$-octatrien-1al))] [3a]. This condensation combines the reaction of 40 with $\mathrm{MeCN} / \mathrm{BuLi}$ and subsequent treatment of the product with DIBAH [3a] into one step (Scheme 4).

From these facts, including the quantitative yield in the step $34 \rightarrow 49$, we conclude that the reason for the unexpected behaviour of 46 can be attributed to the Me group at $\mathrm{C}(3)$. On migration of the metal atom, this substituent would be forced to change from a sterically unhindered to a hindered position. The resulting unfavourable configuration is

[^2]rejected, and the reaction terminates with the formation of 51, rendering a repetition of the sequence according to Scheme 3 impossible. This evidence agrees with the dependance of the yield of complexation on the different constitution of the diene ligand as discussed in 2.1 and illustrates the importance of steric effects in the chemistry of $\left[\mathrm{Fe}(\mathrm{CO})_{3}(\mathrm{diene})\right]$ complexes.
2.2.2. Interconversion of Hydroxymethyl and Carbonyl Groups in the Complexes. As mentioned earlier, sterically hindered aldehydes give poor yields on complexation with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$, whereas the corresponding esters usually exhibit a much better reactivity. On the other hand, the complexation of hydroxymethyl-substituted dienes, which proceeds in good yields, is often accompanied by side reactions and rearrangements which make isolation procedures tedious and time-consuming. Moreover, such ligands are difficult to prepare and handle because of their tendency to form polymers and their sensibility to oxidation. It seems, therefore, desirable to find a convenient way for the interconversion of ester, aldehyde, and hydroxymethyl substituents in the metal complexes. Both the tricarbonyliron complexes of the aldehydes and of the alcohols are of potential interest: the former with respect to chain elongation by aldol-type reactions, and the latter for the preparation of tricarbonyliron-complexed pentadienylium salts [15].

None of the published procedures [16] for the conversion of esters to aldehydes could be adapted to proceed reasonably on the corresponding tricarbonyliron complexes. However, the tricarbonyliron moiety being more or less inert with respect to reagents of the DIBAH type ( $c f$. preparation of 46), the ester function in the complex was reduced to the $\mathrm{CH}_{2} \mathrm{OH}$ substituent with moderate to good yields and the latter oxidized to the aldehyde using $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ on Celite (Fetizon reagent) in benzene (yields ca. $70 \%$ ), the $\mathrm{Fe}(\mathrm{CO})_{3}$ moiety being again unaffected (see 29 $\boldsymbol{\mathbf { 4 1 } \rightarrow \mathbf { 3 7 } \text { , Scheme 5). Sometimes, better }}$ yields of the complexed alcohol were obtained on DIBAH reduction of the complexed aldehyde instead of the ester (see $\mathbf{3 7} \rightarrow \mathbf{4 1}$ ).

41
Analogous transformations were performed in the bis-complexed $\mathrm{C}_{14}$-series (cf. 2.2.4).
2.2.3. Bifunctionalized Diene Complexes. Functionalized $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] complexes such as 39 or 40 can be used in Wittig-type olefinations [17]. For example, the reaction of 39 with isopropylphosphonium bromide/ $\mathrm{NaNH}_{2}[18]$ in THF at $-78^{\circ}$ proceeds smoothly to yield $88 \%$ of the $\eta^{4}$-complexed triene 44 . Furthermore, stereospecific formation $(E)$ of

$39 R^{1}=\mathrm{H}_{1}, \mathrm{R}^{2}=\mathrm{CH}_{3}$
$40 \mathrm{R}^{1}=\mathrm{CH}_{3}, \mathrm{R}^{2}=\mathrm{H}$

44

$54 R^{1}=R^{2}=\operatorname{COOEt}$ $55 \mathrm{R}^{1}=\mathrm{CHO}, \mathrm{R}^{2}=\mathrm{COOEt}$ $56 \mathrm{R}^{1}=\mathrm{COOEt}, \mathrm{R}^{2}=\mathrm{CHO}$ $57 \mathrm{R}^{1}=\mathrm{COOEt}, \mathrm{R}^{2}=\mathrm{CH}_{2} \mathrm{OAC}$
the new double bond can be achieved using the Wittig-Horner method [17] [5e]. To determine the scope of these reactions in polyene natural product synthesis, we prepared and complexed a number of bifunctionalized isoprene derivatives. Their complexation was accomplished by refluxing in $\mathrm{Et}_{2} \mathrm{O}$ with 1.5 equiv. of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$, giving, e.g., 54-57 in $65-85 \%$ yield. As in the case of the monofunctionalized diolefins, the yield depended on the diene substituents showing the following trends: $\mathrm{COOR}>\mathrm{CHO}>\mathrm{CH}_{2} \mathrm{OAc} \gg \mathrm{CN}$. Again, nitriles gave poor yields in complexation reactions.
2.2.4. Mono- and Bis-complexed $C_{14}$-Synthons. Addition of tertiary phosphanes and phosphites to cationic iron complexes give metal-coordinated phosphonium salts and phosphonates which have been used in Wittig and Wittig-Horner reactions [17] [19]. For the preparation of mono- and bis-complexed $\mathrm{C}_{14}$-synthons, we reacted complexed aldehydes first with uncomplexed and then with complexed ylides.

To achieve the stereoselective coupling of two diene synthons in a Wittig-Horner reaction, ethyl 6 -(diethoxyphosphoryl)-4-methyl-2,4-hexadienoate [20] was added to the complexed $\mathrm{C}_{7}$-aldehyde 56 (Scheme 6), giving the mono-complexed $\mathrm{C}_{14}$-diester 59 in $84 \%$ yield. The 'H-NMR coupling constant between $\mathrm{H}-\mathrm{C}(6)$ and $\mathrm{H}-\mathrm{C}(7)(15.6 \mathrm{~Hz})$ suggested $(E)$-configuration for the newly formed double bond.

The reaction of complexed $\mathrm{C}_{7}$-aldehyde $\mathbf{5 6}$ with complexed $\mathrm{C}_{7}$-phosphonate 58 proceeded smoothly to give the bis-complexed $\mathrm{C}_{14}$-diester 60 in $85 \%$ yield (Scheme 5). The $(E)$-configuration of the central $\mathrm{C}=\mathrm{C}$ bond was again confirmed by the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ : analysis of $\mathrm{H}-\mathrm{C}(5), \mathrm{H}-\mathrm{C}(8), \mathrm{H}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(7)\left(A A^{\prime} X X^{\prime}\right.$ spin system) including spectral simulation which gave a value of 14.6 Hz for ${ }^{3} J(\mathrm{H}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(7))$. Reduction of the diester 60 gave the dinuclear $\mathrm{C}_{14}$-diol 61 in $90 \%$ yield and subsequent oxidation the $\mathrm{C}_{14}$-dialdehyde $62(56 \%)$, which can be regarded as a building block for the synthesis of isoprenoid natural products.

The relative position of the two $\mathrm{Fe}(\mathrm{CO})_{3}$ groups in $\mathbf{6 0 - 6 2}$ was not determined. The two protecting groups could be attached to the same face (chiral form) or to opposite faces of the polyene (meso-form). In the case of a similar ( $E$ )-C $\mathrm{C}_{12}$-polyene complex, the X-ray crystal structure has shown that the $\mathrm{Fe}(\mathrm{CO})_{3}$ groups are coordinated to opposite sides of the polyene [17].

These results show that the application of $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene) $]$ synthons in polyene synthesis allows the stereospecific formation of $(E)$-double bonds. This high selectivity suggests that steric interactions between the $\mathrm{Fe}(\mathrm{CO})_{3}$ group of 56 and the approaching ylide result in the formation of the trans-oxaphosphetane intermediate. The successful application of the described reactions to polyene synthesis requires efficient decomplexation methods. A number of mild oxidation reactions have been described [21]. In our experience, best results were achieved with $\mathrm{Ce}\left[\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{NO}_{3}\right)_{6}\right]$ in the two-phase solvent $\mathrm{MeCN} /$ pentane. Complexed nitriles, ketones, and aldehydes have been decomplexed to give the free polyenes in yields of $85-95 \%$ [3a].
3. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR Spectra. - 3.1. Methyl-Substituted [ $\mathrm{Fe}(\mathrm{CO})_{3}($ diene $\left.)\right]$ Complexes. The ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR chemical shifts of $\mathrm{Fe}(\mathrm{CO})_{3}$-complexed methyl-substituted butadienes have been investigated by several authors in comparison to the free dienes and in terms of substituent effects [5b] [22]. However, no direct information on the conformation of complexed diene systems can be gained from chemical-shift data (Table 1). Therefore, we have determined the $\mathrm{H}, \mathrm{H}$ and $\mathrm{C}, \mathrm{H}$ coupling constants (Tables 2 and 3 ) of selected compounds, i.e. 2-4, 9, 11, and 12, in order to reveal geometric distortions imposed on the dienes on complexation. The values obtained for the parent compound of the series, $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (butadiene)] (1) [5a], are used as a reference.

Compared to the free dienes, the vicinal coupling constants ${ }^{3} J(\mathrm{H}, \mathrm{H})$ are reduced in tricarbonyliron complexes. In $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (butadiene) $]$ (1), the reduction amounts to $32 \%$ for the cis coupling $\left({ }^{3} J_{c}\right)$ and to $45 \%$ for the corresponding trans interaction $\left({ }^{3} J_{t}\right)$. On substitution of one or both of the terminal protons $\mathrm{H}_{\mathrm{a}}$ and $\mathrm{H}_{\mathrm{b}}$ by Me groups, a similar decrease of ${ }^{3} J(\mathrm{C}, \mathrm{H})$ compared to the free dienes is observed. However, ${ }^{3} J_{( }(\mathrm{C}, \mathrm{H})$ decreases to a larger extent ( $54-57 \%$ ) than would be expected by comparison with the value for ${ }^{3} J_{t}(\mathrm{H}, \mathrm{H})$ in 1, whereas the reduction of ${ }^{3} J_{t}(\mathrm{H}, \mathrm{H})$ by $c a .30 \%$ is in accordance with the expected range (Table 4). As a consequence of this behaviour, the ${ }^{3} J_{i}(\mathrm{C}, \mathrm{H})$ values of the terminal Me groups of complexed substituted butadienes are smaller than the respective

Table $\left.1 .{ }^{\prime} H_{-}^{-a}\right)$ and ${ }^{I 3} C$-NMR Chemical Shifts ${ }^{\mathrm{b}}$ ) ( $\delta$ [ppm]) of Complexes 2-4, 9, 11, and 12

Table 4. Vicinal H,H and C,H Coupling Constants $\mathrm{J}[\mathrm{Hz}]$ in 1,3-Dienes and their Tricarbonyliron Complexes
(
${ }^{3} J_{c}(\mathrm{C}, \mathrm{H})$ data, a fact that has never been observed so far for olefinic compounds [25] and can only be explained by considerable geometric distortions of $(Z)$-substituted complexes. Me Substitution at one of the central C-atoms ( $c f .4$ ), however, does not lead to an inversion of the $J_{l} / J_{c}$ ratio (Table 3).

Further information can be gained from the study of ${ }^{2} J(\mathrm{H}, \mathrm{H})$ (Table 2) and ${ }^{1} J(\mathrm{C}, \mathrm{H})$ data (Table 3). Both the decrease of ${ }^{2} J(\mathbf{H}, \mathrm{H})$ to negative values (cf. free butadiene: +1.47 $\mathrm{Hz})$ and the fact that the ${ }^{1} J(\mathrm{C}, \mathrm{H})$ values for terminal C -atoms are smaller than those for the central C -atoms indicate a rehybridization of the terminal centers in a sense of increased $\mathrm{sp}^{3}$ character. Similar effects were observed in the ruthenium and osmium analogues of $\mathbf{1}$. The result of these variations in geometry and electron distribution are improved (p-d)-orbital overlap and coordination [5a] [5c].

Finally, we have tried to use ${ }^{1} J(\mathrm{C}, \mathrm{C})$ data as a probe into relative $\mathrm{C}-\mathrm{C}$ bond lengths in complexed dienes. A linear relationship is known to exist between the ${ }^{1} J(\mathrm{C}, \mathrm{C})$ value and the bond length [26], which appears to hold also for organometallic compounds, provided only complexes of the same metal are compared [5c] [27]. The values of ${ }^{1} J(2,3)=43.3$, ${ }^{1} J(3,4)=43.5$, and ${ }^{1} J(4,5)=46.2 \mathrm{~Hz}$ for the olefinic part of complex 2 [5c] (Table 5)

[^3]indicate a very similar bond order for the $\mathrm{C}-\mathrm{C}$ bonds and, therefore, a delocalization of the $\pi$ system. This is in accordance with values obtained by X-ray analysis for similar compounds [28].
3.2. Functionalized $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] Complexes. Complexed butadienes bearing functional groups at the terminal C -atoms exhibit very similar ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR properties compared to the Me-substituted compounds discussed above. However, some additional features seem worth discussing at a more detailed level.

The influence of the functional group on the ${ }^{13} \mathrm{C}$-NMR chemical shift of the carbonyl C-atoms is shown in Table 6. Limiting values for this series have been reported for the complex of 2,4-hexadiene (see Formula 8; 212.9 ppm ) and hexadiene-1,6-dinitrile (205.3 ppm) [29]. The small but characteristic increments correlate with the mesomeric and inductive effects of the substituents. This is in accordance with earlier investigations on symmetrically substituted $\left[\mathrm{Fe}(\mathrm{CO})_{3}(\right.$ diene $\left.)\right]$ complexes where $\delta(\mathrm{CO})$ has been discussed in terms of the Hammett constants of the functional group [29]. The electron density of the diene system is, therefore, reflected in the chemical shift of the carbonyl resonance which in turn can be used as an at least qualitative measure for the amount of $\mathrm{Fe} \rightarrow \mathrm{CO}$ back donation [30].

Table 6. ${ }^{13} \mathrm{C}$-NMR Chemical Shifts ( $\delta$ [ppm], $\mathrm{CDCl}_{3}$ ) of Tricarbonyliron Groups in Functionalized 1,3-Diene Complexes

| $\mathbf{R}-\mathrm{C}(1)$ | Compound | $\delta(\mathrm{Fe}-\mathrm{CO})$ |
| :--- | :--- | :--- |
| Me | $\mathbf{7 , 1 1}$ | $211.9 ; 212.0$ |

| $\mathbf{C H}_{2} \mathrm{OH}$ | $\mathbf{4 1 , \mathbf { 4 2 } , \mathbf { 4 3 }}$ | $211.0 ; 211.0 ; 211.0$ |
| $\mathbf{C H =} \mathbf{C H}-\mathrm{CN}$ | $\mathbf{5 2 , 5 3}$ | $210.2 ; 210.4$ |
| COOR | $\mathbf{2 9 , 3 0}$ | $209.2 ; 209.2$ |
| CHO | $\mathbf{3 7 , 3 8}, \mathbf{3 9}$ | $208.8 ; 208.3 ; 208.6$ |
| CN | $\mathbf{4 9}$ | 208.6 |

As in the case of Me -substituted $\mathrm{Fe}(\mathrm{CO})_{3}$ complexes, bond lengths of selected compounds have been probed by measuring one-bond $\mathrm{C}, \mathrm{C}$ coupling constants. It is known that ${ }^{1} J(\mathrm{C}, \mathrm{C})$ values are sensitive to polarization effects and are influenced by electronegative substituents in uncomplexed compounds, especially if the electron-withdrawing residue is directly connected to the coupled C -atoms [31]. The observed coupling constants of the diene C-atoms, however, are very similar for the compounds taken into consideration (Table 5). This rather surprising result indicates a delocalized $\pi$ system as well as a more or less complete loss of conjugation of the diene system with the functional group. This is in excellent agreement with the observed reactivity of the complexed functionalized dienes with respect to nucleophilic attack as described in [3a].

A further interesting effect can be found by comparing compounds of the same type but with varying position of the Me substituent, e.g. the series $\mathbf{3 7 / 3 8} / \mathbf{3 9}, 29 / 30$, or 41/42/43 (cf. Exper. Part). Whenever the terminal $\mathrm{H}_{\mathrm{a}}$-atom is opposed by a Me group at the C-atom adjacent to the functional group, it experiences a downfield shift of $c a$. $0.5-1.5 \mathrm{ppm}$ in the ${ }^{\prime} \mathrm{H}-\mathrm{NMR}$ spectrum. This effect, obviously due to the steric strain exerted on the ligand by the Me group, can be a helpful tool for the assignment of ${ }^{1} \mathrm{H}$ resonances.

$31 R=M e, R^{\prime}=R^{\prime \prime}=H$
$38 R^{\prime}=M e, R=R^{\prime \prime}=H$
$39 R^{\prime \prime}=M e, R=R^{\prime}=H$

$29 \mathrm{R}=\mathbf{R}^{\prime \prime}=\mathrm{Me}, \mathrm{R}^{\prime}=\mathrm{H}$
$30 \mathrm{R}^{\prime}=\mathrm{Me}, \mathrm{R}^{\prime \prime}=\mathrm{Et}, \mathrm{R}=\mathrm{H}$

$41 R=M e, R^{\prime}=R^{\prime \prime}=H$
$42 \mathrm{R}^{\prime}=\mathrm{Me}, \mathrm{R}=\mathrm{R}^{\prime \prime}=\mathrm{H}$
$43 \mathrm{R}^{\prime \prime}=\mathrm{Me}, \mathrm{R}=\mathrm{R}^{\prime}=\mathrm{H}$

Finally, we have investigated compound 34 with respect to coupling constants. Both ${ }^{3} J(\mathrm{H}, \mathrm{H})$ and ${ }^{3} J(\mathrm{C}, \mathrm{H})$ values correspond to results from similar Me-substituted compounds, e.g. 11 (Tables 2 and 3). In particular, the same inversion of the values of $J_{t} J_{( }(\mathrm{C}, \mathrm{H})$ $(4.2 \mathrm{~Hz})$ and ${ }^{3} J_{c}(\mathrm{C}, \mathrm{H})(4.9 \mathrm{~Hz})$ is observed as for the Me-substituted butadiene series, thus indicating the same steric implications for the Me group irrespective of the functionalization. As will be shown in Chapt.5, the NMR spectroscopic features of 34 in solution correspond to its structure in the solid state as determined by X-ray crystallography.
4. ${ }^{57} \mathrm{Fe}$-NMR Chemical Shifts. - The structural changes in the coordinated diene ligand are also reflected in the ${ }^{57} \mathrm{Fe}$ shielding constants, and the effects may be divided into three major types, i.e. stereoelectronic effects due to direct metal-C coordination, elec-tron-withdrawing effects of substituents on the diene system, and effects associated with a change in the formal charge of the metal complex. The magnitude of the effects increases in the given order.

The stereoelectronic effects can be most clearly recognized in the Me-substituted $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] complexes 2-12 as well as in the cationic Me-substituted $\left[\mathrm{Fe}(\mathrm{CO})_{4}(\mathrm{allyl})\right]\left[\mathrm{BF}_{4}\right]$ complexes 13-25. The ${ }^{57} \mathrm{Fe}-\mathrm{NMR}$ chemical shifts are collected in Tables 7 and 8 (see also [6a]). Me-Substitution on the parent complex 1 always leads to a deshielding of the ${ }^{57} \mathrm{Fe}$ nucleus, and there are characteristic increments $\Delta \delta$ depending on the position of the Me group: $\mathrm{Me}_{\text {trans }}-\mathrm{C}(1)+30 \mathrm{ppm}, \mathrm{Me}_{\text {cis }}-\mathrm{C}(1)+105 \mathrm{ppm}, \mathrm{CH}_{3}-\mathrm{C}(2)$ $+35 \mathrm{ppm},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}(1)+180 \mathrm{ppm}$. The very large deshielding caused by cis configuration of the terminal Me group and $\mathrm{C}(2)-\mathrm{C}(3)$ appears to be a direct consequence of the geometric distortion (rehybridization) at the terminal diene C -atom caused by steric interaction between the $\mathrm{CH}_{3},=\mathrm{C}-\mathrm{H}_{\mathrm{a}}$ and $\mathrm{Fe}(\mathrm{CO})_{3}$ groups. Increased s-contribution in the $\mathrm{C}(1,4)-\mathrm{Fe}$ bonding corresponds to an increased back-bonding or decrease in the HOMO-LUMO gap with an increase of the paramagnetic shielding term [7c]. Similar deshielding effects of the ${ }^{59} \mathrm{Co}$ resonance have already been described for $\left[\mathrm{Co}\left(\eta^{5}\right.\right.$-indenyl)(diene)] complexes with a cis-configurated Me group at $\mathrm{C}(1)$ [6a]. The Me substituent

[^5]effects are additive which is most clearly demonstrated in the series of substituted $\left[\mathrm{Fe}(\mathrm{CO})_{4}\left(\eta^{3}\right.\right.$-allyl) $)\left[\mathrm{BF}_{4}\right]$ complexes (see 13, 20, and 25; cf. Table 8). In this series of cationic complexes, also inductive effects of Me groups can be observed leading to a shielding of the ${ }^{57} \mathrm{Fe}$ nucleus, e.g. in $\mathbf{2 3}$ as compared to $\mathbf{2 0}(\Delta \delta(\mathrm{Fe})=-11.6 \mathrm{ppm})$.

The effect of electron-withdrawing substituents on the diene system is associated with a strong deshielding of the ${ }^{57} \mathrm{Fe}$ resonance as shown by the data given in Table 9. The high-frequency shift increases in the series $\mathrm{COOR}<\mathrm{COCH}_{3}<\mathrm{CHO}<\mathrm{CN}$, which correlates qualitatively with the electron-withdrawing power of the substituent. The largest effects are observed when the substituent X is directly attached to the Fe -atom, i.e. in the series of $\left[\mathrm{FeX}(\mathrm{CO})_{3}\left(\eta^{3}\right.\right.$-allyl) $]$ complexes given in Fig. $I$ (see Table 8). We learn from these data that ${ }^{57} \mathrm{Fe}$ shielding decreases with increasing electronegativity of the halogen atom in

a semiquantitative manner. In addition, for the iodo complex 28, the two stereoisomers, known to be in a slow exchange on the NMR time scale [32], show different chemical shifts ( $\Delta v=1.56 \mathrm{kHz}$ at 12.9 MHz ). The very large deshielding effects in $\mathbf{2 6 - 2 8}$ are certainly due, at least in part, to an increase in the effective positive charge at the Fe -atom. Other cationic dienyl- and trienyliron complexes also measured in $\mathrm{CF}_{3} \mathrm{COOH}$ appear in the same resonance range, i.e. 680-1440 ppm (Table 10).

Compound $\quad \delta(\mathrm{Fe}) \quad$ Compound

Finally, the coordination of a carbonyl O -atom to the Fe -atom, exemplified in the $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-enone $\left.)\right]$ complexes 63-73 results in large deshielding effects of 1200-1700 ppm relative to $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-butadiene $\left.)\right]$ ( $\mathbf{1}$; Table 11). Heterodiene coordination to an $\mathrm{Fe}(\mathrm{CO})_{3}$ moiety can, therefore, easily be detected by ${ }^{13} \mathrm{C}-\mathrm{NMR}$ (cf. 2.1) and ${ }^{57} \mathrm{Fe}-\mathrm{NMR}$ spectroscopy. A comparison of the propenal complex 63 with the butenone complex 68 again shows the deshielding effect of the Me group on the ${ }^{57} \mathrm{Fe}$ nucleus ( +49 ppm ), but in general, Me substituent effects are small in this series ( $<15 \mathrm{ppm}$ ).

Also reported in Tables $7-9$ are the ratios $T_{1} / T_{2}$ of the ${ }^{57} \mathrm{Fe}$ spin-lattice and spin-spin relaxation times which were obtained in the field $B_{0}=2.114 T$ from the dependence of the steady-state signal amplitudes on the flip angle [34]. In a recent detailed relaxation study [35], including compounds 1-4, the experimental relaxation rates $T_{1}^{-1}$ determined at 2.9 $\mathrm{MHz}\left(B_{\mathrm{o}}=2.1 T\right)$ and $12.9 \mathrm{MHz}\left(B_{\mathrm{o}}=9.4 T\right)$ were analyzed for contribution from different relaxation mechanisms. Spin-rotation (SR) and chemical-shift anisotropy (CSA) combined with molecular reorientation were pointed out to be the dominating mechanisms while contributions from all other relaxation mechanisms were negligible. Assuming SR and CSA to be the dominating mechanisms for the longitudinal relaxation of all compounds in Tables $7-9$, a ratio $T_{1} / T_{2} \approx 1$ points out that the transverse relaxation is exclusively due to the same mechanisms. A ratio $T_{1} / T_{2}>2$, however, is an indication for additional contributions to $T_{2}^{-1}$ arising from e.g. fluxionality of the complex or adsorption of the molecule to colloidal or visible paramagnetic particles in the sample.

[^7]coordinates are given in Table 12. As expected, 34 exhibits geometrical features similar to those observed in other $\left[\mathrm{Fe}(\mathrm{CO})_{3}(\mathrm{diene})\right.$ ] compounds [3d] [28]. Very similar distances $C(3)-C(4), C(4)-C(5)$, and $C(5)-C(6)$ indicate a more or less complete equilibration of bond orders in the diene subsystem. This is in agreement with the one-bond, $\mathrm{C}, \mathrm{C}$ coupling constants ${ }^{1} J(\mathrm{C}, \mathrm{C})$ obtained for related compounds in solution (cf. Chapt. 3.2, Table 5). Further evidence for a delocalized $\pi$-system is provided by the planarity of the diene system, the largest distance of the C -atoms $\mathrm{C}(3)$ to $\mathrm{C}(6)$ from their mean plane being $0.016 \AA$.

The substituents at $\mathbf{C}(3)$ and $C(6)$, however, do not occupy positions in the plane defined by the diene system. In particular, $\mathrm{C}(8)$ and $\mathrm{H}-\mathrm{C}(3)$ are twisted out of the $\pi$-plane to a considerable extent (Table 13). This effect has also been observed in other substituted $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] complexes investigated by X-ray crystallography [3d] [36] [37], irrespective of the nature of the substituent. We, therefore, conclude that the conformational distortion in 34 is mainly caused by steric interaction between $\mathrm{H}-\mathrm{C}(3)$ and the 'syn'-oriented $\mathrm{Me}-\mathrm{C}(6)$, and by a similar interaction of this Me group and $\mathrm{H}-\mathrm{C}(3)$, respectively, with the Fe -atom. The latter effect is reflected in the distances $\mathrm{Fe}-\mathrm{C}(6)(2.213(3) \AA)$ and $\mathrm{Fe}-\mathrm{C}(3)(2.120(2) \AA)$. This interpretation has recently been corroborated by force-field calculations [37].

Table 13. Selected Torsional Angles ( ${ }^{\circ}$ ) in the Two Independent Molecules $\mathbf{a}$ and $\mathbf{b}$ of $\mathbf{3 4}$

|  | Structure element | a | b |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}(2)-\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{C}(5)$ | 164.8 | 167.3 |  |
| $\mathrm{H}-\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{C}(5)$ | -41 | -41 |  |
| $\mathrm{C}(4)-\mathrm{C}(5)-\mathrm{C}(6)-\mathrm{C}(7)$ | -163.4 | -162.4 |  |
| $\mathrm{C}(4)-\mathrm{C}(5)-\mathrm{C}(6)-\mathrm{C}(8)$ | 52.4 | 53.4 |  |

The large deviation from planarity of $\mathrm{C}(8)$ forces $\mathrm{C}(7)$ to adopt a position nearer to the Fe -atom. However, the out-of-plane distortion is considerably smaller than for $\mathrm{C}(8)$ (Table 13). This in turn leads to torsional angles of $5^{\circ}$ for $\mathrm{H}-\mathrm{C}(5)-\mathrm{C}(6)-\mathrm{C}(7)$ and $140^{\circ}$ for $\mathrm{H}-\mathrm{C}(5)-\mathrm{C}(6)-\mathrm{C}(8)$, thus yielding an explanation for the unusual ${ }^{3} J(\mathrm{C}, \mathrm{H})$ values of substituted $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (diene)] complexes reported in Chapts. 3.1 and 3.2, i.e., ${ }^{3} J_{i}<{ }^{3} J_{c}$. With some restrictions, $\mathbf{3 4}$ can be described to exhibit a square-pyramidal geometry with one of the carbonyl groups of the $\mathrm{Fe}(\mathrm{CO})_{3}$ moiety in the apical position and the Fe -atom in the center of the pyramid.

## Experimental Part

1. Instrumental. NMR spectra: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ Varian EM-390 ( 90 MHz ), XL-200 ( 200 MHz ), and Bruker AM-400 $(400 \mathrm{MHz}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}$ Varian $X L-100(25.2 \mathrm{MHz}), X L-200(50.4 \mathrm{MHz})$, and Bruker $A M-400(100.6 \mathrm{MHz})$; ${ }^{57} \mathrm{Fe}$-NMR Bruker $A M-400(12.9 \mathrm{MHz})$, and home-built spectrometer ( 2.9 MHz ) described in [5d] [38]; J(H,H) and $J(\mathrm{C}, \mathrm{H})$ in Tables 2 and 3 from complete analysis of the multi-spin systems including iterative computer simulation using the PANIC program (Bruker); accuracy of $J(\mathrm{H}, \mathrm{H})$ and $J(\mathrm{C}, \mathrm{H}), \pm 0.25 \mathrm{~Hz}$, of $J(\mathrm{C}, \mathrm{C}), \pm 0.5 \mathrm{~Hz}$; ${ }^{1} \mathrm{H}$-NMR in $5-\mathrm{mm}$ tubes, ${ }^{13} \mathrm{C}$-NMR in $10-\mathrm{mm}$ tubes, and ${ }^{57} \mathrm{Fe}$-NMR spectra in $20-\mathrm{mm}(12.9 \mathrm{MHz})$ or $22-\mathrm{mm}$ tubes $(2.9 \mathrm{MHz}) ; \delta(\mathrm{Fe})$ relative to $\mathrm{Fe}(\mathrm{CO})_{5}$ as an external standard, $\delta(\mathrm{H})$ and $\delta(\mathrm{C})$ relative to internal TMS; deuterated
solvents were degassed and stored over aluminium oxide, and the samples were prepared under $\mathrm{N}_{2}$ and sealed; $J(\mathrm{C}, \mathrm{C})$ 's were determined with the ${ }^{13} \mathrm{C}$-isotope in natural abundance using the INADEQUATE pulse sequence [39] or by a combination of INADEQUATE and INEPT [40], in both cases at 50.3 MHz , or with a conventional FT technique at 25.2 MHz with double precision data acquisition; estimated errors smaller than $\pm 0.5 \mathrm{~Hz}$; ambiguous assignments of ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ data are indicated by an asterisk. Mass spectra: Varian MAT 711 at 70 eV .
2. X-Ray Crystallographic Study. Tricarbonyl $[3-6-\eta-($ ( E)-6-methyl-3,5-heptadien-2-one) $]$ iron (34), $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{FeO}_{4}$, mol. wt. 264.06, crystallized from hexane $/ \mathrm{Et}_{2} \mathrm{O} 1: 1$ at $-20^{\circ}$ in orange-yellow triclinic crystals of space group $P 1$ with two independent molecules in the asymmetric unit cell, $a=9.083(1), b=11.791(1), c=11.856(1)$ $\left.\AA ; \alpha=97.83(1), \beta=95.36(1), \gamma=99.90(1)^{\circ}\right) ; D_{\text {cak. }}=1.43 \mathrm{~g} / \mathrm{cm}^{3}$. The intensity of 4563 reflections within $\lambda^{-1} \cdot \sin \theta<0.60 \AA^{-1}$ were measured on a Nicolet-R3 diffractometer in the $\omega$-scan technique using graphite monochromatized $\mathrm{Mo}_{\alpha}$ radiation. They were averaged to 4334 symmetry-independent reflections after the usual corrections except for absorption were applied. Both structure solution (heavy-atom method) and refinement were performed using the SHELXTL program [41]. All H-atoms were localized using difference electron density calculations and varied with isotropic temperature factors while the other atoms were refined with anisotropic temperature factors. In the last blocked cascade refinement (with ca. 100 variables per block), the 3982 unique structure factors with $F>1 \sigma_{F}$ were used to bring the 385 variables to convergence at $R=0.041, w R=0.049$, $1 / w=\sigma_{F}^{2}+0.001 F^{2}$.
3. Syntheses. (Butadiene)tricarbonyliron was purchased from Strem Chemicals and used without further purification. The following compounds were synthesized according to procedures given in the literature: 2-5, 7-12 [42]; 26-28[43]; 31, $\mathbf{4 0}$ [44]; 32, $33[45] ; 45,4748,50[3 \mathrm{a}] ; 63,67,68,71-73$ [46] [11]. All preparations were carried out under $\mathrm{N}_{2}$ in dry, $\mathrm{O}_{2}$-free solvents. The products were filtered over $\mathrm{Al}_{2} \mathrm{O}_{3}$ (aluminiumoxid 90 , stand., act. II-III, $70-230$ mesh; Merck $A G$ ) prior to chromatography. Chromatographic separations were performed on silica gel 60 ( $70-230$ mesh, Merck $A G$ ) under atmospheric pressure. Traces of solvents were removed at r.t. $/ 10^{-3}$ Torr after purification. M. p.: Kofler apparatus, uncorrected.
4. General Procedure for the Complexation of Functionalized Dienes. A Schlenk-type flask is charged with 15 $\mathrm{mmol}(5.46 \mathrm{~g})$ of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ [47]. $\mathrm{O}_{2}$ is removed by alternating evacuation with a water-jet pump and refilling with $\mathrm{N}_{2}$. Then, 50 ml of benzene (distilled from Na and made $\mathrm{O}_{2}$-free by bubbling $\mathrm{N}_{2}$ through the distillate for 10 min ) and 10 mmol of the freshly distilled functionalized diene are added in a $\mathrm{N}_{2}$ counter current. The mixture is gently refluxed under stirring in a weak stream of $\mathrm{N}_{2}$ for $6-10 \mathrm{~h}$ (TLC control, silica gel, hexane/ $\mathrm{Et}_{2} \mathrm{O} 2: 1$ ). Then, the mixture is allowed to cool to r.t. and evaporated. The crude complexes are worked up as indicated for the specific compounds.

In some cases, yields are increased by adding more $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ after $c a$. half the reaction time. Using a larger amount of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ at the beginning of the reaction has no influence on the yields.
5. General Procedure for the Synthesis of $\left[\mathrm{Fe}(\mathrm{CO})_{3}\right.$ (heterodiene)] Complexes. At $40-45^{\circ}, 50 \mathrm{mmol}$ of the heterodiene and $55-60 \mathrm{mmol}$ of $\mathrm{Fe}(\mathrm{CO})_{5}$ were irradiated overnight with a high-pressure mercury lamp (Philips $H P K, 125 W)$. By TLC, 2 products could be detected, the $\left[\mathrm{Fe}(\mathrm{CO})_{4}\left(\eta^{2}\right.\right.$-heterodiene $\left.)\right]$ and the $\left[\mathrm{Fe}(\mathrm{CO})_{3}\left(\eta^{4}\right.\right.$-heterodiene)] complex. The benzene soln. was filtered through Celite to remove any decomposed material and then refluxed to convert the ene complex into the enone complex. Removal of the solvent and chromatography on silica gel yielded the pure compounds in $60-80 \%$ yield.
6. Butadiene Complexes. Tricarbonyl/ $1-4-\eta-((Z)-3$-methyl-1,3-pentadiene )]iron (6) was prepared according to Exper. 4 and the general procedures in [5e]. ${ }^{57} \mathrm{Fe}$-NMR: Table $7 .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 105.2(\mathrm{C}(3))$; 89.9 (C(2)); $56.0(\mathrm{C}(4)) ; 37.3(\mathrm{C}(3)) ; 25.1(\mathrm{Me}-\mathrm{C}(3)) ; 13.5\left(\mathrm{Me}_{\mathrm{a}}-\mathrm{C}(4)\right)$.

Tricarbonyll $2-5-\eta$-(methyl (E)-2-methyl-2,4-pentadienoate)]iron (29). According to Exper.4, 0.92 g ( 7.3 mmol ) of methyl ( E )-2-methyl-2,4-pentadienoate [48] are treated with an excess of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$. When no more starting material can be detected by TLC $\left(\mathrm{Et}_{2} \mathrm{O} /\right.$ hexane $\left.1: 19\right)$, most of the solvent is removed and the resulting slurry transferred to a column of $\mathrm{Al}_{2} \mathrm{O}_{3}$. Apolar impurities are removed by elution with hexane. Rinsing the column with $\mathrm{Et}_{2} \mathrm{O}$ and evaporation of the solvent yield $1.28 \mathrm{~g}(67 \%)$ of 29 as an orange oil. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ : $6.16(d, \mathrm{H}-\mathrm{C}(3)) ; 5.49(d d d, \mathrm{H}-\mathrm{C}(4)) ; 3.70(s, \mathrm{COOMe}) ; 2.00\left(d, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 1.89\left(d, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) ; 1.10(\mathrm{~s}, \mathrm{Me}-\mathrm{C}(2))$. ${ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 209.2\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 175.2(\mathrm{C}(1)) ; 91.6,88.6(\mathrm{C}(3), \mathrm{C}(4) *) ; 56.4(\mathrm{C}(2)) ; 51.6(\mathrm{COOMe}) ;$ 41.7 (C(5)); $14.2(M e-\mathrm{C}(2))$. MS: $266\left(2, M^{+}\right), 238(11), 210(22), 182(57), 127(100), 56(46)$.

[^8]Tricarbonyl/2-5- $\eta$-(ethyl (E)-3-methyl-2,4-pentadienoate) ]iron (30). According to Exper. $4,1.4 \mathrm{~g}(10 \mathrm{mmol})$ of ethyl ( E )-3-methyl-2,4-pentadienoate ${ }^{6}$ ) are reacted with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ in benzene. After $2 \mathrm{~h}, 2.5 \mathrm{~g}$ of additional $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ are added. After all starting material has disappeared ( $\mathrm{TLC}, \mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 19$ ), the solvent is evaporated and the crude product dissolved in $\mathrm{Et}_{2} \mathrm{O}$ and filtered over $\mathrm{Al}_{2} \mathrm{O}_{3}$. Chromatography of the filtrate on silica gel with $\mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 19$ yields $2.30 \mathrm{~g}(82 \%)$ of 30 as a yellow oil. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 5.18(d d, \mathrm{H}-\mathrm{C}(4)) ; 4.10(q$, $\mathrm{COOCH}_{2} \mathrm{CH}_{3}$ ); $2.54(s, \mathrm{Me}-\mathrm{C}(3)) ; 1.80\left(d d, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 1.26\left(t, \mathrm{COOCH}_{2} \mathrm{CH}_{3}\right) ; 0.28(s, \mathrm{H}-\mathrm{C}(2)) ; 0.49$ (dd, $\left.\mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 209.2\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 171.4(\mathrm{C}(1)) ; 104.3(\mathrm{C}(3)) ; 85.7(\mathrm{C}(4)) ; 59.9$ $\left(\mathrm{COOCH}_{2} \mathrm{CH}_{3}\right) ; 48.6(\mathrm{C}(2)) ; 38.2(\mathrm{C}(5)) ; 18.6(\mathrm{Me}-\mathrm{C}(3)) ; 14.1\left(\mathrm{COOCH}_{2} \mathrm{CH}_{3}\right) . \mathrm{MS}: 280\left(5, \mathrm{M}^{+}\right), 252(14), 224$ (21), 196 (49), 124 (100), 56 (24).

Tricarbonyl $3-6-\eta$-( ( E)-6-methyl-3,5-heptadien-2-one) Jiron (34). According to Exper. $4,2.48 \mathrm{~g}(20 \mathrm{mmol})$ of (E)-6-methyl-3,5-heptadien-2-one [50] are complexed. The crude produt is filtered over a short column of $\mathrm{Al}_{2} \mathrm{O}_{3}$ and chromatographed twice on silica gel. In the 1st run using hexane $/ \mathrm{Et}_{2} \mathrm{O} 1: 1$, a deep red fraction $\left(R_{\mathrm{f}} 0.50\right)$ is collected and identified as tricarbonyl/ $\mathrm{O}-4-\eta-((\mathrm{E})-6$-methyl-3,5-heptadien-2-one) yiron ( $\mathbf{3 5}$ ) by NMR (cf. Chapt. 2.1). The yellow band at $R_{\mathrm{f}} 0.30$ consists of 34 and unreacted starting material and has to be separated in a 2 nd run with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Recrystallization of the yellow fraction from pentane at $-78^{\circ}$ yields $2.16 \mathrm{~g}(41 \%)$ of 34 . M.p. $53^{\circ}$. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): 5.69(d d, \mathrm{H}-\mathrm{C}(4)) ; 4.42(d, \mathrm{H}-\mathrm{C}(5)) ; 2.17(d, \mathrm{H}-\mathrm{C}(3)) ; 1.76(s, \mathrm{Me}-\mathrm{C}(2)) ; 1.13(s$, $\left.\mathrm{Me}_{\mathrm{b}}-\mathrm{C}(6)\right) ; \quad 0.82 \quad\left(s, \quad \mathrm{Me}_{\mathrm{a}}-\mathrm{C}(6)\right) ; \quad{ }^{3} J(\mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(4))=8.7 ; \quad{ }^{3} J(\mathrm{H}-\mathrm{C}(4), \mathrm{H}-\mathrm{C}(5))=5.5 ; \quad{ }^{4} J(\mathrm{H}-\mathrm{C}(3)$, $\mathrm{H}-\mathrm{C}(5))=0.1 .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(100.8 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): 208.1\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 199.0(\mathrm{C}(2)) ; 92.1$ (C(5)); 86.8 (C(4)); 74.9 $(\mathrm{C}(6)) ; 57.0 \quad(\mathrm{C}(3)) ; 36.0 \quad\left(M e_{\mathrm{b}}-\mathrm{C}(6)\right) ; 32.4 \quad(\mathrm{C}(1)) ; 25.0 \quad\left(M e_{\mathrm{a}}-\mathrm{C}(6)\right) ;{ }^{3} J\left(M e_{\mathrm{a}}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(5)\right)=4.2$; ${ }^{3} J\left(M e_{\mathrm{b}}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(5)\right)=4.9 . \mathrm{MS}: 236\left(4, M^{+}\right), 208(6), 180(17), 140(10), 124$ (18), 109 (100), 81 (46), 43 (56). Anal. calc. for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{FeO}_{4}$ : C $50.00, \mathrm{H} 4.55$; found: $\mathrm{C} 50.30, \mathrm{H} 4.80$.

Tricarbonyl/ $2-5-\eta-($ ( E)-2-methyl-2,4-pentadienal) firon (37). According to Exper. $4,1.92 \mathrm{~g}$ ( 20 mmol ) of (E)-2-methyl-2,4-pentadienal [51] are treated with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ in benzene. The crude complex is filtered over $\mathrm{Al}_{2} \mathrm{O}_{3}$ $\left(\mathrm{Et}_{2} \mathrm{O}\right)$ and chromatographed on silica gel $\left(\mathrm{Et}_{2} \mathrm{O}\right.$ /hexane $\left.1: 1\right)$. The yellow band at $R_{\mathrm{f}} 0.35$ is collected and the solvent is removed. Recrystallization from pentane at $-78^{\circ}$ yields $0.70 \mathrm{~g}(15 \%)$ of 37. M.p. $30^{\circ}$. ${ }^{1} \mathrm{H}-\mathrm{NMR}(90 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right): 8.91(s, \mathrm{H}-\mathrm{C}(1)) ; 5.34-5.67(m, \mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(4)) ; 1.88-2.32\left(m, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 1.30-1.60\left(m, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) ; 1.60$ $(s, \mathrm{Me}) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 208.8\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 193.0(\mathrm{C}(1)) ; 92.0,88.8\left(\mathrm{C}(3), \mathrm{C}(4)^{*}\right) ; 71.7(\mathrm{C}(2)) ; 43.6$ (C(5)); 21.8 (Me). MS: 208 (3, $M^{+}-\mathrm{CO}$ ), $180(8), 152$ (16), 96 (23), $67(65), 56(52), 39$ (100). Anal. calc. for $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{FeO}_{4}: \mathrm{C} 45.76, \mathrm{H} 3.39$; found: C $45.61, \mathrm{H} 3.13$.

Tricarbonyl $\left[2-5-\eta-((\mathrm{E})-3-m e t h y l-2,4-\right.$ pentadienal $)$ Jiron (38). Under $\mathrm{N}_{2}, 4.6 \mathrm{~g}$ of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ on Celite ( 1 mmol $\mathrm{Ag}_{2} \mathrm{CO}_{3} / 0.57 \mathrm{~g}, 8 \mathrm{mmol}$ ) [ 52 ] are suspended in 40 ml of abs. benzene. Residual moisture is removed by azeotropic distillation of $c a .10 \mathrm{ml}$ of the solvent. After cooling to r.t., $180 \mathrm{mg}(0.8 \mathrm{mmol})$ of 42 in 10 ml of abs. benzene are added, and the mixture is refluxed until all 42 has disappeared ( $c a .30 \mathrm{~min} ; \mathrm{TLC}, \mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 2$ ). The mixture is filtered, the solvent evaporated, and the raw product chromatographed on a short column of silica gel ( $\mathrm{Et}_{2} \mathrm{O} / \mathrm{hex}-$ ane 1:2): $130 \mathrm{mg}(70 \%)$ of yellow oil. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 9.57(d, \mathrm{H}-\mathrm{C}(1)) ; 5.28(d d, \mathrm{H}-\mathrm{C}(4)) ; 2.53(s$, $\mathrm{Me}) ; 2.00\left(d d, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 1.10(d, \mathrm{H}-\mathrm{C}(2)) ; 0.90\left(d d, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 208.3\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ;$ $195.5(\mathrm{C}(1)) ; 103.7(\mathrm{C}(3)) ; 86.9(\mathrm{C}(4)) ; 58.4(\mathrm{C}(2)) ; 39.4(\mathrm{C}(5)) ; 19.2(\mathrm{Me}) . \mathrm{MS}: 236\left(5, \mathrm{M}^{+}\right), 208(8), 180(40), 152$ (72), 56 (100).

Tricarbonyll $2-5-\eta-($ ( $)$-4-methyl-2,4-pentadienal) Jiron (39). According to Exper. $4,0.8 \mathrm{~g}(8.3 \mathrm{mmol})$ of ( E )-4-methyl-2,4-pentadienal [51] are reacted with $4.55 \mathrm{~g}(12.5 \mathrm{mmol})$ of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ in 50 ml of benzene. The raw mixture is dissolved in $\mathrm{Et}_{2} \mathrm{O}$ and filtered over a short column of $\mathrm{Al}_{2} \mathrm{O}_{3}$ to remove polar impurities und unreacted $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$. After evaporation, the residue is chromatographed on silica gel with $\mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 3\left(R_{\mathrm{f}} 0.20\right)$. Evaporation yielded $1.0 \mathrm{~g}(51 \%)$ of 39 as a red oil which solidified on standing and was recrystallized from pentane at $-78^{\circ}$. M.p. $34^{\circ}{ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 9.35(d, \mathrm{H}-\mathrm{C}(1)) ; 5.81(d, \mathrm{H}-\mathrm{C}(3)) ; 2.22(\mathrm{~s}, \mathrm{Me}) ; 2.12\left(\mathrm{~s}, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right)$; $1.11(d d, \mathrm{H}-\mathrm{C}(2)) ; 0.89\left(s, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 208.6\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 196.0(\mathrm{C}(1)) ; 103.8(\mathrm{C}(4)) ;$ $84.4(\mathrm{C}(3)) ; 53.5(\mathrm{C}(2)) ; 44.8(\mathrm{C}(5)) ; 22.4(\mathrm{Me}) . \mathrm{MS}: 236\left(10, M^{+}\right), 208(21), 180(64), 152(75), 134(59), 96(29), 56$ (100). Anal. calc. for $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{FeO}_{4}$ : C 45.76, H 3.39; found: C 45.90, H 3.64.

Tricarbonyl [ $2-5-\eta-((\mathrm{E})$-2-methyl-2,4-pentadien-1-ol) ]iron (41). Using the procedure described for the synthesis of 43,41 is prepared from $0.53 \mathrm{~g}(2 \mathrm{mmol})$ of 29. Chromatography on silica gel ( $\mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 1$ ) of the product obtained from the $\mathrm{Al}_{2} \mathrm{O}_{3}$-filtration step yields $240 \mathrm{mg}(50 \%)$ of 41 . ${ }^{1} \mathrm{H}$-NMR ( $90 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $5.35(s$,
${ }^{6}$ ) The pure ( $E$ )-isomer was prepared by the reaction of $35.8 \mathrm{~g}(0.1 \mathrm{~mol})$ of methyltriphenylphosphonium bromide, $62.5 \mathrm{ml}(0.1 \mathrm{~mol})$ of $\mathrm{BuLi}(1.6 \mathrm{~N}$ in hexane) and $13.6 \mathrm{ml}(0.1 \mathrm{~mol})$ of ethyl 3-methyl-4-oxocrotonate (Fluka $A G$ ), according to the general procedure for Wittig olefinations, in $33 \%$ yield. The spectroscopic data are in agreement with published values, see e.g. [49].
$\mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(4)) ; 3.63(d, \mathrm{H}-\mathrm{C}(1)) ; 2.20(t, \mathrm{OH}) ; 1.5-2.0\left(m, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5), \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 1.20(\mathrm{~s}, \mathrm{Me}) .{ }^{13} \mathrm{C}-\mathrm{NMR}(25.2$ $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right): 211.0\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 91.1,86.4\left(\mathrm{C}(3), \mathrm{C}(4)^{*}\right) ; 73.2(\mathrm{C}(1)) ; 41.5(\mathrm{C}(5)) ; 15.7(\mathrm{Me}) . \mathrm{MS}: 210(2$, $M^{+}-\mathrm{CO}$ ), 182 (4), 154 (5), 56 (40), 40 (100).

Tricarbonyl/ $2-5-\eta-((E)-3-m e t h y l-2,4-p e n t a d i e n-1-o l) /$ iron (42). Using the procedure described for the synthesis of $\mathbf{4 3}, \mathbf{4 2}$ is prepared from $0.56 \mathrm{~g}(2 \mathrm{mmol})$ of $\mathbf{3 0}$. Chromatography of the product obtained from the $\mathrm{Al}_{2} \mathrm{O}_{3}$-filtration step on silica gel ( $\mathrm{Et}_{2} \mathrm{O} /$ hexane $1: 1$ ) yields $230 \mathrm{mg}(48 \%)$ of $\mathbf{4 2}$. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 5.16$ $(d d, \mathrm{H}-\mathrm{C}(4)) ; 3.80(d, \mathrm{H}-\mathrm{C}(1)) ; 2.22(\mathrm{~s}, \mathrm{Me}) ; 2.00(\mathrm{br} . s, \mathrm{OH}) ; 1.62\left(d d, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 0.92(t, \mathrm{H}-\mathrm{C}(2)) ; 0.50(d d$, $\left.\mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 211.0\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 102.5(\mathrm{C}(3)) ; 83.5(\mathrm{C}(4)) ; 61.7(\mathrm{C}(1)) ; 61.7(\mathrm{C}(2)) ; 37.5$ (C(5)); 18.1 (Me). MS: $238\left(31, M^{+}\right), 210(42), 182(39), 154$ (67), 136 (100), 56 (67).

Tricarbonyl/ $2-5-\eta-($ ( E)-4-methyl-2,4-pentadien-1-ol) ]iron (43). To $300 \mathrm{mg}(1.27 \mathrm{mmol})$ of 39 in 20 ml of $\mathrm{Et}_{2} \mathrm{O}$ at $-78^{\circ}$ under $\mathrm{N}_{2}$ (septum), $3.0 \mathrm{ml}(3 \mathrm{mmol})$ of 1 N DIBAH in hexane is added dropwise under stirring. After the addition is complete, the mixture is allowed to warm up to r.t. The workup procedure is identical to that for 46 . However, chromatography is not necessary since filtration over $\mathrm{Al}_{2} \mathrm{O}_{3}$ yields $280 \mathrm{mg}(93 \%)$ of pure $\mathbf{4 3}$. ${ }^{'} \mathrm{H}-\mathrm{NMR}$ $\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 5.28(d, \mathrm{H}-\mathrm{C}(3)) ; 3.70(d, \mathrm{H}-\mathrm{C}(1)) ; 2.19(s, \mathrm{Me}) ; 2.19(s, \mathrm{OH}) ; 1.78\left(s, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(5)\right) ; 0.92(d t$, $\mathrm{H}-\mathrm{C}(2)) ; 0.50\left(s, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(5)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) ; 211.0\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 100.5(\mathrm{C}(4)) ; 86.6(\mathrm{C}(3)) ; 64.7(\mathrm{C}(1)) ;$ $58.7(\mathrm{C}(2)) ; 43.7(\mathrm{C}(5)) ; 22.7(\mathrm{Me}) . \mathrm{MS}: 238\left(2, \mathrm{M}^{+}\right), 210(7), 182(9), 154(17), 134(58), 81(85), 79(97), 42(100), 41$ (99).

Tricarbonyl/ $1-4-\eta$-( ( E)-2,6-dimethyl-1,3,5-heptatriene) Jiron (44). At r.t. under $\mathrm{N}_{2}, 4.13 \mathrm{~g}$ of isopropylphosphonium bromide $/ \mathrm{NaNH}_{2}(9.5 \mathrm{mmol}$; 'instant-ylide', Fluka $A G)$ are stirred in 40 ml of THF for 2 h . The mixture is chilled to $-78^{\circ}$, and $2.24 \mathrm{~g}(9.5 \mathrm{mmol})$ of 39 in 10 ml of THF are added dropwise by means of a syringe. The cooling bath is removed and stirring continued at r.t. until almost all starting material has disappeared (ca. 3 h ; TLC, $\mathrm{Et}_{2} \mathrm{O} /$ hexane 1:3). The resulting black mixture is diluted with 30 ml of $\mathrm{H}_{2} \mathrm{O}$, acidified with 5 ml of conc. $\mathrm{HCl} / \mathrm{H}_{2} \mathrm{O}$ $1: 1$, and the deep red org. layer is separated. The aq. layer is extracted 3 times with hexane, the org. layers are combined, and the solvent is evaporated. The residue is washed several times with small portions of hexane and filtered from the insoluble $\mathrm{Ph}_{3} \mathrm{PO}$. The combined washings ( $c a .50 \mathrm{ml}$ ) are further purified by filtration over a column of $\mathrm{Al}_{2} \mathrm{O}_{3}$. Elution with hexane yields $2.19 \mathrm{~g}(88 \%)$ of 44 which can be recrystallized from pentane at $-78^{\circ}$. M.p. $26-27^{\circ} .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(90 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 5.24,5.21$ ( $\left.2 d, \mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(5)^{*}\right) ; 2.17$ ( $\mathrm{s}, \mathrm{Me}-\mathrm{C}(2)$ ); $1.80(d d$, $\mathrm{H}-\mathrm{C}(4)) ; 1.80\left(d, \mathrm{H}_{\mathrm{b}}-\mathrm{C}(1)\right) ; 1.70(s, 2 \mathrm{Me}-\mathrm{C}(6)) ; 0.50\left(d, \mathrm{H}_{\mathrm{a}}-\mathrm{C}(1)\right) . \quad{ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 211.9$ $\left(\mathrm{Fe}(\mathrm{CO})_{3}\right) ; 134.8(\mathrm{C}(6)) ; 126.6(\mathrm{C}(5)) ; 98.5(\mathrm{C}(2)) ; 86.0(\mathrm{C}(3)) ; 58.1(\mathrm{C}(4)) ; 42.3(\mathrm{C}(1)) ; 26.0,22.9,18.4$ ( $\left.\mathrm{Me}-\mathrm{C}(2), 2 \mathrm{Me}-\mathrm{C}(6)^{*}\right) . \mathrm{MS}: 262\left(2, M^{+}\right), 234$ (7), 206 (7), 178 (23), 122 (11), 112 (18), 84 (52), 56 (100). $\mathrm{Me}-\mathrm{C}(4)) ; 2.08(\mathrm{~s}, \mathrm{Ac}) ; 1.24\left(t, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 1.21(t, J=7.0$, hidden, $\mathrm{H}-\mathrm{C}(5)) ; 1.01(d, J=7.9, \mathrm{H}-\mathrm{C}(2))$. ${ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) ; 172.1\left(\mathrm{COCH}_{3}\right) ; 170.3(\mathrm{C}(1)) ; 85.2(\mathrm{C}(4)) ; 79.1(\mathrm{C}(3)) ; 63.1(\mathrm{C}(6)) ; 60.5$ $\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 56.8(\mathrm{C}(5)) ; 44.5(\mathrm{C}(2)) ; 20.7\left(\mathrm{COCH}_{3}\right) ; 18.1(\mathrm{C}(7)) ; 14.2\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right) . \mathrm{MS}: 324\left(2, M^{+}-\mathrm{CO}\right), 296$ (6), 268 (48), 208 (43), 108 (62), 80 (100).

Tricarbonyl/2-5- $\eta$-(ethyl (2E,4E)-6-(diethoxyphosphoryl)-4-methyl-2,4-hexadienoate) Jiron (58). Photolysis of ethyl 6-(diethoxyphosphoryl)-4-methyl-2,4-hexadienoate [20] using $\mathrm{Fe}(\mathrm{CO})_{5}$ (see Exper.4) yields $70 \%$ of 58 as a red oil. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 5.74(d, J=7.9, \mathrm{H}-\mathrm{C}(3)) ; 4.20-4.0\left(\mathrm{~m}, 2 \mathrm{H}-\mathrm{C}(6), \mathrm{OCH}_{2} \mathrm{CH}_{3}\right.$, $\left.\mathrm{PO}\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)_{2}\right) ; 2.24(t, J=5.6, \mathrm{H}-\mathrm{C}(5)) ; 2.22(s, \mathrm{Me}-\mathrm{C}(4)) ; 1.35(t d, J(\mathrm{P}, \mathrm{H})=1,5, J(\mathrm{H}, \mathrm{H})=7.0$, $\left.\mathrm{PO}\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)_{2}\right) ; 1.25\left(t, J=7.1, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 0.97(d, J=7.9, \mathrm{H}-\mathrm{C}(2)) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(50.4 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 209.3$ $(\mathrm{CO}) ; 172.3(\mathrm{C}(1)) ; 101.8(d, J(\mathrm{P}, \mathrm{C})=9.8, \mathrm{C}(4)) ; 84.5(\mathrm{C}(3)) ; 61.8\left(d, J(\mathrm{P}, \mathrm{C})=14.4, \mathrm{PO}\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)_{2}\right) ; 60.4$ $\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 53.0(d, J(\mathrm{P}, \mathrm{C})=6.9, \mathrm{C}(5)) ; 43.9(\mathrm{C}(2)) ; 28.5(d, J(\mathrm{P}, \mathrm{C})=140.3, \mathrm{C}(6)) ; 18.4(\mathrm{C}(7)) ; 16.3(d$, $\left.J(\mathrm{P}, \mathrm{C})=5.8, \mathrm{PO}\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)_{2}\right) ; 14.1\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$.

Tricarbonyl[2-5- $\boldsymbol{\eta}$-(diethyl $(2 \mathrm{E}, 4 \mathrm{E}, 6 \mathrm{E}, 8 \mathrm{E}, 10 \mathrm{E})-4,9$-dimethyl-2,4,6,8,10-dodecapentaenedioate) ]iron (59). A soln. of 580 mg ( 2 mmol ) of ethyl ( $E$ )-6-(diethoxyphosphoryl)-4-methyl-2,4-hexadienoate [20] in 25 ml of dry THF is cooled to $-78^{\circ}$, and $1.2 \mathrm{ml}(1.92 \mathrm{mmol})$ of $\mathrm{BuLi}(1.6 \mathrm{~m}$ in hexane) are slowly added. The dark red soln. containing the ylide is warmed to $-50^{\circ}$ and then re-cooled to $-78^{\circ}$. At this temp., $540 \mathrm{mg}(1.77 \mathrm{mmol})$ of 56 in 15 ml of THF are slowly added, the soln. is kept at $-70^{\circ}$ for 5 h and then allowed to warm overnight to $5^{\circ}$. Neutralization with $10 \%$ HCl soln. and extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ give, after flash chromatography on silica gel $\left(\mathrm{Et}_{2} \mathrm{O} /\right.$ hexane $\left.2: 1\right), 0.66 \mathrm{~g}$ ( $84 \%$ ) of 59. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 7.35(d, J=15.6, \mathrm{H}-\mathrm{C}(10)) ; 6.71(d d, J=14.5,11.6, \mathrm{H}-\mathrm{C}(7)) ; 6.37(d$, $J=11.6, \mathrm{H}-\mathrm{C}(8)) ; 6.15(d d, J=14.5,10.8, \mathrm{H}-\mathrm{C}(6)) ; 5.93(d, J=15.6, \mathrm{H}-\mathrm{C}(11)) ; 5.73(d, J=8.4, \mathrm{H}-\mathrm{C}(3)) ; 4.23$ $\left(q, J=7.2, \mathrm{C}(12) \mathrm{OOCH}_{2} \mathrm{CH}_{3}\right)^{*} ; 4.14\left(m, \mathrm{C}(1) \mathrm{OOCH}_{2} \mathrm{CH}_{3}\right)^{*} ; 2.32(s, \mathrm{Me}-\mathrm{C}(4)) ; 2.15(d, J=10.8, \mathrm{H}-\mathrm{C}(5)) ; 1.89$ $(s, \mathrm{Me}-\mathrm{C}(9)) ; 1.36-1.24\left(2 t, 1 d, 2 \mathrm{COOCH}_{2} \mathrm{CH}_{3}, \mathrm{H}-\mathrm{C}(2)\right) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(50.4 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 209.1$ (CO); 172.5 ( $\mathrm{C}(1)) ; 166.9(\mathrm{C}(12)) ; 148.5(\mathrm{C}(10)) ; 137.2(\mathrm{C}(6)) ; 136.2(\mathrm{C}(8)) ; 133.6(\mathrm{C}(9)) ; 128.2(\mathrm{C}(7)) ; 117.1(\mathrm{C}(11)) ; 99.6$ $(\mathrm{C}(4)) ; 84.6(\mathrm{C}(3)) ; 65.1(\mathrm{C}(5)) ; 60.6,60.3\left(\mathrm{COOCH}_{2} \mathrm{CH}_{3}\right) ; 43.9(\mathrm{C}(2)) ; 19.2$ ( $\left.\mathrm{Me}-\mathrm{C}(4)\right) ; 14.4,14.3$ $\left(\mathrm{COOCH}_{2} \mathrm{CH}_{3}\right) ; 12.7(\mathrm{Me}-\mathrm{C}(9)) . \mathrm{MS}: 444\left(2, \mathrm{M}^{+}\right), 416(3), 388(10), 360(52), 240(80) 128$ (100).
7. Bis(tricarbonyliron) Complexes. Hexacarbonyl[ $2-5-\eta: 8-11-\eta$-(diethyl ( $2 \mathrm{E}, 4 \mathrm{E}, 6 \mathrm{E}, 8 \mathrm{E}, 10 \mathrm{E}$ )-4,9-di-methyl-2,4,6,8,10-dodecapentaene-1,12-dioate ) ]diiron ( 60 ). A soln. of $0.86 \mathrm{~g}(2 \mathrm{mmol})$ of 58 in 25 ml of dry THF is cooled to $-78^{\circ}$, and $1.25 \mathrm{ml}(1.92 \mathrm{mmol})$ of $\mathrm{BuLi}(1.6 \mathrm{M}$ in hexane) are slowly added. The dark red ylide soln. is warmed to $-50^{\circ}$ and then re-cooled to $-78^{\circ}$. At $-78^{\circ}, 0.6 \mathrm{~g}(1.9 \mathrm{mmol})$ of 56 in 15 ml of THF are slowly added, and the soln. is kept at $-70^{\circ}$ for 5 h and then allowed to warm overnight to $5^{\circ}$. Neutralization with $10 \% \mathrm{HCl}$ soln. and extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ give, after flash chromatography on silica gel ( $\mathrm{Et}_{2} \mathrm{O} /$ hexane $2: 1$ ), $0.9 \mathrm{~g}(85 \%)$ of $\mathbf{6 0}$. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 6.08\left(A A^{\prime}\right.$ of $\left.A A^{\prime} X X^{\prime}, J=14.4,10.6,-0.81, \mathrm{H}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(7)\right) ; 5.69(d, J=7.8$, $\mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(10)) ; 4.13\left(m, 2 \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 2.31(\mathrm{~s}, \mathrm{Me}-\mathrm{C}(4), \mathrm{Me}-\mathrm{C}(9)) ; 2.04\left(X X^{\prime}\right.$ of $A A^{\prime} X X^{\prime}, J=14.4,10.6$, $-0.81, \mathrm{H}-\mathrm{C}(5), \mathrm{H}-\mathrm{C}(8)) ; 1.26\left(t, 2 \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 1.19(d, J=7.8, \mathrm{H}-\mathrm{C}(2), \mathrm{H}-\mathrm{C}(11)) .{ }^{13} \mathrm{C}-\mathrm{NMR}(50.4 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right): 209.3(\mathrm{CO}) ; 172.4(\mathrm{C}(1), \mathrm{C}(12)) ; 131.3(\mathrm{C}(6), \mathrm{C}(7)) ; 99.1(\mathrm{C}(4), \mathrm{C}(9)) ; 84.1(\mathrm{C}(3), \mathrm{C}(10)) ; 65.2(\mathrm{C}(5), \mathrm{C}(8))$; $60.5\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ; 43.7(\mathrm{C}(2), \mathrm{C}(11)) ; 19.0(\mathrm{Me}-\mathrm{C}(4), \mathrm{Me}-\mathrm{C}(9)) ; 14.2\left(\mathrm{OCH}_{2} \mathrm{CH}_{3}\right) . \mathrm{MS}: 584\left(4, M^{+}\right), 556(1), 528$ (9), 500 (15), 472 (15), 444 (53), 416 (100).

Hexacarbonyll $2-5-\eta: 8-11-\eta-((2 \mathrm{E}, 4 \mathrm{E}, 6 \mathrm{E}, 8 \mathrm{E}, 10 \mathrm{E})-4,9$-dimethyl-2,4,6,8,10-dodecapentaene-1,12-diol) 1 diiron ( 61 ). To a soln. of $0.4 \mathrm{~g}(0.7 \mathrm{mmol})$ of 60 in 25 ml of THF, cooled to $-78^{\circ}, 1.2 \mathrm{ml}(1.2 \mathrm{mmol})$ of DIBAH (1m in hexane) are added dropwise. On completion of the reaction (TLC), 3 ml of MeOH are added to remove excess DIBAH. Subsequently, the mixture is hydrolyzed first with sat. $\mathrm{NH}_{4} \mathrm{Cl}$ soln. and then with $10 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ soln. Extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and filtration over a short $\mathrm{Al}_{2} \mathrm{O}_{3}$ column give $315 \mathrm{mg}(90 \%)$ of $61 .{ }^{1} \mathrm{H}-\mathrm{NMR}(200 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right): 5.99\left(A A^{\prime}\right.$ of $\left.A A^{\prime} X X^{\prime}, J=14.4,10.6, \mathrm{H}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(7)\right) ; 5.07(d, J=8.2, \mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(10)) ; 3.76-3.62$ $(2 m, 2 \mathrm{H}-\mathrm{C}(1), 2 \mathrm{H}-\mathrm{C}(12)) ; 2.23(s, \mathrm{Me}-\mathrm{C}(4), \mathrm{Me}-\mathrm{C}(9)) ; 1.85\left(X X^{\prime}\right.$ of $\left.A A^{\prime} X X^{\prime}, J=14.4,10.6, \mathrm{H}-\mathrm{C}(5), \mathrm{H}-\mathrm{C}(8)\right)$; $1.23(t d, J=8.2,7.4, \mathrm{H}-\mathrm{C}(2), \mathrm{H}-\mathrm{C}(11)) .{ }^{13} \mathrm{C}-\mathrm{NMR}\left(50.4 \mathrm{MHz},\left(\mathrm{D}_{6}\right)\right.$ acetone $): 212.7(\mathrm{CO}) ; 132.2(\mathrm{C}(6), \mathrm{C}(7)) ; 97.8$ (C(4), C(9)); $85.4(\mathrm{C}(3), \mathrm{C}(10)) ; 66.3(\mathrm{C}(2), \mathrm{C}(11)$ or $\mathrm{C}(5), \mathrm{C}(8)) ; 64.5(\mathrm{C}(5), \mathrm{C}(8)$ or $\mathrm{C}(2), \mathrm{C}(11)) ; 60.5(\mathrm{C}(1), \mathrm{C}(12))$; 19.0 ( $\mathrm{Me}-\mathrm{C}(4), \mathrm{Me}-\mathrm{C}(9)$ ). MS: $500\left(4, M^{+}\right), 472(2), 444$ (6), 416 (15), 388 (2), 360 (3), 332 (26), 148 (100).

Hexacarbonyl $/ 2-5-\eta: 8-11-\eta-((2 \mathrm{E}, 4 \mathrm{E}, 6 \mathrm{E}, 8 \mathrm{E}, 10 \mathrm{E})-4,9$-dimethyl-2, 4, 6, 8, 10-dodecapentaenedial) $)$ diiron (62). A soln. of $0.1 \mathrm{~g}(0.2 \mathrm{mmol})$ of 61 in 5 ml of dry benzene is added to a slurry of $\mathrm{Ag}_{2} \mathrm{CO}_{3} /$ Celite [52] in benzene. The mixture is refluxed for 3 h ( $\rightarrow$ black; no 61 left). The mixture is then filtered through Celite and evaporated. Some decomposition products are removed by chromatography on silica gel (hexane/ $\mathrm{Et}_{2} \mathrm{O}$ 1:1) which yields $56 \mathrm{mg}(56 \%)$ of $62 .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 9.32(d, J=4.3, \mathrm{H}-\mathrm{C}(1), \mathrm{H}-\mathrm{C}(12)) ; 6.18\left(A A^{\prime}\right.$ of $A A^{\prime} X X^{\prime}$, $J=14.6,10.8,-0.71, \mathrm{H}-\mathrm{C}(6), \mathrm{H}-\mathrm{C}(7)) ; 5.67(d, J=8.1, \mathrm{H}-\mathrm{C}(3), \mathrm{H}-\mathrm{C}(10)) ; 2.31(s, \mathrm{Me}-\mathrm{C}(4), \mathrm{Me}-\mathrm{C}(9)) ; 2.30$ $\left(X X^{\prime}\right.$ of $\left.A A^{\prime} X X^{\prime}, J=14.6,10.8,-0.71, \mathrm{H}-\mathrm{C}(5), \mathrm{H}-\mathrm{C}(8)\right) ; 1.48(d d, J=8.1,4.3, \mathrm{H}-\mathrm{C}(2), \mathrm{H}-\mathrm{C}(11)) .{ }^{13} \mathrm{C}-\mathrm{NMR}$ ( $50.4 \mathrm{MHz},\left(\mathrm{D}_{6}\right)$ acetone): 196.5 ( $\left.\mathrm{C}(1), \mathrm{C}(12)\right) ; 131.3(\mathrm{C}(6), \mathrm{C}(7)) ; 100.4(\mathrm{C}(4), \mathrm{C}(9)) ; 82.5(\mathrm{C}(3), \mathrm{C}(10)) ; 65.7$
(C(5), $\mathrm{C}(8)$ ); 52.1 (C(2), C(11)); 19.1 (Me-C(4), Me-C(9)). MS: $496\left(4, M^{+}\right), 440(2), 412$ (15), 384 (3), 356 (3), 328 (17), 182 (95), 68 (100).
8. Heterodiene Complexes. The following heterodiene complexes $\mathbf{6 4 - 6 6 , 6 9}$, and 70 were prepared according to Exper. 5 and characterized by ${ }^{13} \mathrm{C}$ - and ${ }^{57} \mathrm{Fe}$-NMR data (cf. Table 11).

Tricarbonyl/ $\mathrm{O}-3-\eta-\left(\right.$ (E)-2-methylpropenal) Jiron (64). ${ }^{13} \mathrm{C}-\mathrm{NMR}\left(25.2 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): 208.7$ (CO); 123.8 (C(1)); $102.7(\mathrm{C}(2)) ; 45.7(\mathrm{C}(3)) ; 16.5(M e-\mathrm{C}(2))$.

[^0]:    ${ }^{1}$ ) Transition-Metal NMR Spectroscopy, Part XI. Part X: [1].

[^1]:    ${ }^{2}$ ) Indicative for the enone mode of complexation are the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR signals for an uncomplexed double bond as well as the low-frequency shift of the ${ }^{13} \mathrm{C}$ resonance of $\mathrm{C}(2)$.
    ${ }^{3}$ ) $\quad \mathrm{As}$ in the case of 35 , the signals of an uncomplexed bond $(\mathrm{C}(2)=\mathrm{C}(3))$ are observed in the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra.

[^2]:    ${ }^{4}$ ) Attempts to synthesize 34 by Friedel-Crafts acetylation of the tricarbonyliron complex 11 of 2-methyl-2,4pentadiene failed. We ascribe this fact to steric hindrance caused by one of the Me group at $\mathrm{C}(2)$ which interferes with the Ac group in the ( $Z$ )-isomer of 34 which is initially formed on acetylation [14].

[^3]:    ${ }^{\text {a }}$ ) Numbering of the C -atoms was unified to facilitate comparison of data.
    ${ }^{\text {b }}$ ) Not obtained.
    ${ }^{\text {c }}$ From [5c].

[^4]:    ${ }^{\text {a }}$ ) Determined at 12.9 MHz and $(296 \pm 1) \mathrm{K}$; all other data at 2.9 MHz and $(300 \pm 1) \mathrm{K}$.
    ${ }^{\text {b }}$ ) From [5d].
    ${ }^{\text {c }}$ ) Determined at 2.9 MHz and 295 K .

[^5]:    ${ }^{\text {a }}$ ) Determined at 2.9 MHz and $(300 \pm 1) \mathrm{K} ; 26$ and 28 at 12.9 MHz and $(296 \pm 1) \mathrm{K}$.
    ${ }^{b}$ ) Decomposition of sample during measurement did not permit determination.
    ${ }^{9}$ ) From [5d].
    ${ }^{d}$ ) For assignment of stereoisomers, see Fig. 1 and [32].

[^6]:    ${ }^{\text {a }}$ ) Measured at 273 K .

[^7]:    ${ }^{\text {a }}$ ) Equivalent isotropic $U$ defined as one third of the trace of the orthogonalized $U$ tensor.

[^8]:    ${ }^{5}$ ) Calculated from $2 \theta$ values of 64 automatically centered reflection positions of a hemisphere with $40^{\circ}<|2 \theta|<46^{\circ}$.
