Role of Torsional Dynamics on Hole and Exciton Stabilization in π -Stacked Assemblies: Design of Novel Rigid Torsionomers of a Cofacial Bifluorene

Denan Wang, Maxim V. Ivanov, Damian Kokkin, John Loman, Jin-Zhe Cai, Scott A. Reid* and Rajendra Rathore[†]

In memory of Rajendra Rathore

Abstract: Efficient exciton and charge delocalization across π stacked assemblies is of critical importance in biological systems and functional polymeric materials. To examine the requirements for exciton and hole stabilization, we report the design, synthesis, and characterization of a novel set of cofacial bifluorene (F2) torsionomers: unhindered (model) MeF2, sterically hindered BuF2, and cyclophane-like ^cF2, where fluorenes are rigidly locked in a perfect sandwich orientation via two methylene linkers. This set of carefully designed bichromophores with varied torsional rigidity and orbital overlap shows that exciton stabilization requires a perfect sandwich-like arrangement, as evidenced by strong excimeric-like emission only in ${}^{\rm C}\!F2$ and ${}^{\rm Me}\!F2.$ In contrast, hole delocalization is less geometrically restrictive and occurs even in sterically hindered ^{Bu}F2, as judged by 160 mV hole stabilization and a near-IR band in the spectrum of its cation radical. These findings underscore the diverse requirements for charge and energy delocalization across π -stacked assemblies.

Charge and energy dynamics across π -stacked assemblies is of critical importance in biological systems as well in the performance of functional materials.¹⁻³ Various π -stacked dimers capable of excimer formation and charge-resonance stabilization based upon benzene,⁴⁻⁸ fluorene,⁹⁻¹² pyrene^{13,14} and other aromatic donors¹⁵⁻¹⁸ have served as model systems to gain fundamental insight into key factors controlling charge/energy stabilization. These studies have established that the extent of the cationic charge (i.e., hole) and exciton stabilization/delocalization is dependent on the orbital overlap between the chromophores, and is optimal when the π -stacked assembly adopts a perfect sandwich-like arrangement, where orbital overlap and electronic coupling are at their maxima.^{10,11}

Building upon this work, recent studies comparing a model covalently linked fluorene dimer **F**2 with the van der Waals dimer of fluorene, (**F**)₂, have shown that the geometrical requirements for hole and exciton stabilization are distinct.^{10,11} In particular, while their ionization potentials (IPs) are identical, excimeric emission at the sandwich-like geometries is shifted to longer wavelength in **F**2 as compared to (**F**)₂. Thus, a slight displacement from the ideal overlap leads to a less stabilized excimer in (**F**)₂, while cation radical stabilization remains unchanged. In the same context, in covalently linked

polyfluorenes (**F***n*, n = 2-7) the cationic charge is delocalized over multiple fluorenes,^{19,20} while exciton delocalization is limited to two fluorenes.²¹

Figure 1. A. The electronic coupling and relative energy of F2 calculated using B1LYP40-D3/6-31G(d)+PCM(CH₂Cl₂) along the intrinsic reaction coordinate connecting two displaced conformations. The structure with the maximal coupling and energy is a transition state with the imaginary frequency (*i*12.1 cm⁻¹) corresponding to the torsional motion. **B.** Schematic representation of the torsional mode in F2. Incorporation of a methylene linker (i.e., ^CF2) and substituents (i.e., ^{Me}F2 and ^{HBu}F2) produces various torsionomers of F2.

Importantly, the dynamics of hole and exciton transfer in Fn is modulated by a low-frequency torsional mode between adjacent units, as evidenced in the broad and largely unresolved band in the gas-phase excitation spectrum of F2.¹⁰ Indeed, calculations show that the activation barrier for interconversion between two mirror images displaced conformers of F2 is only 3 kcal/mol, yet the electronic coupling along the interconversion coordinate varies between 0.0-0.3 eV (Figure 1A).

In order to probe the effect of cofaciality on the hole and exciton stabilization in π -stacked systems, we synthesized three rigid torsionomers of F2, i.e., cofacial bifluorenes that differ by the extent of their cofaciality along the torsional coordinate via methylene linkers or substituents (Figure 1B). In a cyclophane-like bifluorene ^cF2, a pair of four-methylene linkers ensures that the relative arrangement of fluorenes is nearly identical to that found in the excimer and dimer cation radical of unsubstituted F2. In contrast, bulky *t*Bu groups in ^{fBu}F2 guarantee that the sandwich-like arrangement is highly energetically unfavorable due to increased steric hindrance. We then compare the redox

COMMUNICATION

and optoelectronic properties of the two torsionomers with those of model monomeric ${}^{\rm Me}F1/{}^{\rm Bu}F1$ and model bichromophoric ${}^{\rm Me}F2$ whose geometrical properties are nearly identical to those of unsubstituted F2.

The bifluorene ^RF2H2 precursor was generated by the condensation reaction between readily available^{22,23} ^RF and 0.5 equivalent of paraformaldehyde with potassium *tert*-butyl oxide catalyst (Scheme 1A). Desired bi- and mono-fluorenes (i.e., ^RF2 and ^RF1) are readily produced through the methylation of ^RF2H2/^RF with Mel and potassium *tert*-butyl oxide as base (Scheme 1A/B). Synthesis of ^CF2 was carried out by following the procedure shown in Scheme 1C. First, the intermediate ^{Br4}F2

was generated by condensation of 2,7-dibromofluorene into ^{Br4}F2H2 followed by its methylation. The bromide was then converted to a boron ester using Pd(dppf)Cl₂ catalyst, which was reacted with allyl bromide to produce ^{Al4}F2. Intramolecular olefin metathesis reaction allowed us to prepare the ^CF2 precursor in good yield, which was then subjected to Pd/C catalyzed hydrogenation, producing ^CF2 as a final product. The ^RF2 and ^CF2 torsionomers and their model compounds ^RF1 were fully characterized by ¹H/¹³C NMR spectroscopy (Figure 2A) and X-ray crystallography (Figure 2B); see Supporting Information for full details.

Figure 2. A. Partial ¹H NMR spectra of ^{Me}F2, ^{Bu}F2 and ^cF2 in CDCl₃ at 22 °C. B. ORTEP diagrams (50% diagram) of ^{Me}F2, ^{Bu}F2 and ^cF2 highlighting varied cofaciality of the torsionomers.

The characteristic absorption bands in the electronic spectra of ^CF2. ^{Me}F2 and ^{Bu}F2 are comprised of similar vibronic features and the wavelength of the absorption maximum is nearly invariant, i.e., $\lambda_{max} = 272\pm 2$ nm (Figure 3). In contrast, emission spectra of F2 derivatives display a strong dependence on the cofaciality between fluorene mojeties (Figure 2). First, emission spectrum of ^cF2 shows a broad excimeric-like band at 402 nm with the lifetime (T) of 3.8 ns. While the emission spectrum of MeF2 displays a similar excimeric band at 400 nm (T = 6.5 ns), it also contains a weak band at 325 nm (τ = 2.4 ns), which corresponds to the region where emission of MeF1 monomer occurs (Figure S3 in the Supporting Information). This indicates that two minima must be present on the potential energy surface (PES) of the S₁ excited state of ^{Me}F2. Indeed, TD-DFT calculations at the benchmarked^{12,24,25} B1LYP40-D3/6-31G(d)+PCM(CH₂Cl₂) revealed the presence of two equilibrium structures of MeF2 on the excited state PES, with different exciton delocalization as represented by the transition-density plots in Figure 3. In the global-minimum excimeric sandwich-like structure, the exciton is delocalized over both fluorenes, while in the higher-energy displaced MeF2, the exciton is localized on a single fluorene.

Figure 3. Absorption (grey) and emission (colored) spectra of $^c\text{F2}$, $^{\text{Me}}\text{F2}$ and $^{\text{fBu}}\text{F2}$ in CH₂Cl₂ at at 22 °C. Sticks represent the emission wavelength calculated using TD-B1LYP40-D3/6-31G(d)+PCM(CH₂Cl₂). Transition-density plots are shown for the equilibrium structures of $^c\text{F2}$, $^{\text{Me}}\text{F2}$ and $^{\text{fBu}}\text{F2}$.

In contrast to unhindered ^{Me}F2, the emission spectrum of sterically hindered ^{#Bu}F2 displays strong monomeric and weak excimeric bands at 325 and 380 nm, with corresponding lifetimes of 0.4 ns and 1.5 ns, respectively. This suggests that the steric hindrance imposed by the bulky *t*Bu groups must destabilize a sandwich-like conformation in favor of the conformation where two fluorenes are displaced. Indeed, TD-DFT calculations showed the presence of two energetically similar equilibrium structures on the excited state PES of ^{#Bu}F2, corresponding to a sandwich-like conformation with exciton delocalized over both fluorenes and a displaced conformation with exciton fully localized on a single fluorene (Figure 3).

Cyclic voltammograms of ^CF2, ^{Me}F2 and ^{Bu}F2 show (Figure 4A) two reversible oxidation waves, with the first oxidation potential (E_{ox}) increasing *gradually* from 0.66 to 0.77 to 0.86 V vs Fc/Fc⁺, respectively. Comparison with the appropriate model compounds (^{Me}F1 and ^{Bu}F1) shows that stabilization of the

cationic charge, i.e., $\Delta E_{ox} = E_{ox}({}^{R}F1) - E_{ox}({}^{R}F2)$, is largest for ${}^{C}F2$ ($\Delta E_{ox} = 360 \text{ mV}$) and decreases as the concomitant energetic penalty of adopting a sandwich-like arrangement increases in ${}^{Me}F2$ ($\Delta E_{ox} = 250 \text{ mV}$) and ${}^{Bu}F2$ ($\Delta E_{ox} = 160 \text{ mV}$). Despite the significant steric hindrance imposed by *t*Bu groups in {}^{Bu}F2, the hole stabilization of 160 mV remains significant, highlighting our prior finding that a hole can be stabilized even when there is a minimal orbital overlap.^{10,11}

Figure 4. A. Cyclic voltammograms of 2 mM ^CF2, ^{Me}F2, ^{Bu}F2 (solid lines) and their corresponding monomeric model compounds (dashed lines) in CH₂Cl₂ (0.1 m *n*-Bu₄NPF₆) at a scan rate of 100 mVs⁻¹ and 22°C. B. Electronic absorption spectra of ^CF2⁺⁺, ^{Me}F2⁺⁺ and ^{Bu}F2⁺⁺ in CH₂Cl₂ at 22°C. Sticks represent excitation wavelength calculated using TD-B1LYP40-D3/6-31G(d)+PCM(CH₂Cl₂); dark colour corresponds to the sandwich-like structure and light colour corresponds to the displaced structure of ^RF2.

We generated the cation radicals of ${}^{\text{Me}}\text{F2}, \, {}^{\text{fBu}}\text{F2},$ and ${}^{\text{C}}\text{F2}$ via quantitative²⁶ redox titrations using robust aromatic oxidants [THEO⁺⁺][SbCl₆⁻] and NAP⁺⁺SbCl₆ (see details in the Supporting Information).²⁷ Reproducible spectra of both ^CF2⁺⁺ and ^{Me}F2⁺⁺ show a nearly identical intense intervalence band centered at 1418 nm (Figure 4B), signifying that the MeF2+ structure is identical to that of CF2+, i.e. corresponding to a sandwich-like arrangement of fluorenes, and the cationic charge is delocalized over both fluorenes via strong through-space electronic coupling. Indeed, (TD)-DFT calculations confirmed that the intense near-IR band corresponds to sandwich-like conformations of CF2+ and MeF2+, where the charge/spin is delocalized over both fluorenes (Figure 4B). Our calculations also predict a displaced conformation of ${}^{Me}F2^{+}$ that lies 1.4 kcal/mol higher in energy than the sandwich-like structure, and also displays spin/charge delocalization over both fluorenes, suggesting that even a minimal through-space orbital overlap is sufficient to promote hole delocalization in bifluorenes. This lies in contrast to the

COMMUNICATION

excited state of ^{Me}F2, where in the displaced conformation the exciton is localized on a single fluorene (Figure 3).

The electronic spectrum of ${}^{\rm tBu}\text{F2}^{**}$ shows a much less intense intervalence band that is shifted to longer wavelength (2400 nm), suggesting a reduced electronic coupling and/or increased reorganization energy in ${}^{\rm tBu}\text{F2}^{**}$ as compared to those in ${}^{\rm c}\text{F2}^{**}$ and ${}^{\rm Me}\text{F2}^{**}$. DFT calculations showed that two energetically similar (ΔG = 3.5 kcal/mol) conformations of ${}^{\rm tBu}\text{F2}^{**}$ may exist. The sandwich-like arrangement displays a significant puckering of the fluorene moieties due the steric hindrance from bulky fBu groups, yet the spin/charge remains delocalized over both fluorenes. In the displaced ${}^{\rm tBu}\text{F2}^{**}$, the spin/charge is largely localized on a single fluorene, due to the significant displacement and therefore reduced orbital overlap/electronic coupling.

Additional insights come from gas-phase spectra of the three torsionomers, obtained via laser induced fluorescence (LIF) spectroscopy using a heated supersonic nozzle; details are provided in the Supporting Information. As shown in Figure 5, the differences in these spectra are striking. The spectrum of ^{Me}F2 is similar to that of F2 in displaying a broad and largely unresolved profile (Figure 5A); the breadth is explained in the terms of an underlying progression in the torsional motion which is broadened by the fast dynamics and strong modulation of the electronic coupling (Figure 1A). The underlying progression is clearly seen in the spectrum of ${}^{{}_{tBu}}\!F\!2$ (Figure 5B), absent any spectral broadening. On the other hand, the spectrum of ^cF2 (Figure 5C) is both sharp and distinct, and strikingly red-shifted. Here, the torsional libration is guenched and the Franck-Condon active vibration corresponds to a "breathing" type motion of the two subunits (see Figure S14 in Supporting Information). The dramatic consequences of steric hindrance in the BuF2 derivative can be further seen in a comparison with unsubstituted F2 (Figure 5D). Here, the underlying torsional progression is clearly evidenced, as the breadth of the spectra is similar. A more detailed analysis of these spectra is beyond the scope of this article and will be reported in future.

Figure 5. Laser induced fluorescence spectra of ^{Me}F2 (green), ^{Bu}F2 (blue), ^CF2 (red) and F2 (black) in the gas-phase. Sharp transitions in the spectrum of ^{Me}F2 reflect monomeric impurity. Comparison of the LIF spectra of F2 (black) with ^{Bu}F2 (blue) shows the underlying torsional progression.

In this study, we have used a set of novel torsionomers to examine the contrasting requirements for exciton and hole stabilization in π -stacked assemblies. Exciton stabilization requires a perfect sandwich-like arrangement, as evidenced by the presence of strong excimeric-like emission only in ^CF2 and ^{Me}F2. In contrast, cationic charge can be delocalized even for structures where the path to cofaciality is sterically hindered, i.e. ^{fBu}F2, as judged by the 160 mV hole stabilization and the presence of a near-IR transition in its cation radical spectrum. These findings underscore important design principles for next generation optoelectronic materials.
