Anal. Calcd. for C<sub>18</sub>H<sub>86</sub>O<sub>2</sub>: neut. equiv., 284. Found: neut. equiv., 283.

The acid was identified as stearic acid by mixed m.p. with an authentic specimen, and by preparation of the p-phenylphenacyl ester, m.p. and mixed m.p. with an authentic sample  $97^{\circ}$ .

Oxidation of Scabrin.—To a stirred suspension of 1.8 g. of scabrin in 120 ml. of water, maintained at 60°, 11.6 g. of finely powdered potassium permanganate (equivalent to 10 moles of oxygen) was added in small portions. When the reaction mixture had become colorless, the manganese dioxide was filtered and washed thoroughly with warm water. The combined aqueous filtrates were concentrated down to 35 ml. and made acid to congo red with sulfuric acid. The solution was steam distilled to remove completely the volatile acids and then extracted with ether in a continuous extractor. The ether solution was freed of solvent, and the partly crystalline residue was subjected to sublimation in a micro sublimator. Five hundred and seventy mg. of color-less solid was obtained, which sublimed at  $100-110^{\circ}$  (15 mm.) and melted at  $185-186^{\circ}$  (dec.). It rapidly reduced an aqueous solution of potassium permanganate.

Anal. Calcd. for C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>: neut. equiv., 45. Found: neut. equiv., 45.

The substance was identified as anhydrous oxalic acid by a mixture melting point determination with an authentic specimen (m.p.  $186-187^{\circ}$  dec.) and by preparation of the dip-phenylphenacyl ester, m.p. and mixed m.p. with authentic material 165.5° (dec.).

The yield of oxalic acid was 58% (1.16 moles). The sublimation residue, after recrystallization from ethyl acetate, yielded 561 mg. of colorless crystals, m.p. 187-188°.

Anal. Calcd. for C<sub>4</sub>H<sub>6</sub>O<sub>4</sub>: neut. equiv., 59. Found: neut. equiv., 58.

The substance was identified as succinic acid by a mixture melting point determination, m.p. 187.5-188.0°, and by preparation of the di-p-phenylphenacyl ester, m.p. 208°. An additional 220 mg. of succinic acid (total yield 61%, 1.22 moles) was obtained from the ethyl acetate mother liquors, together with a tarry residue which could not be made to crystallize, and which was obviously polymerized material.

The solution of steam-volatile acids obtained above was neutralized with sodium hydroxide solution, concentrated to a small volume on the steam-bath, and acidified to congo red with sulfuric acid. The solution was rapidly steam distilled until all material acid to congo red had distilled over. The distillate was neutralized with 0.1 N NaOH solution (47.50 ml. was required), the neutral solution was evaporated It melted at 82° and a mixed melting point determination with authentic p-phenylphenacyl butyrate, m.p. 82°, showed no depression. The yield of butyric acid, therefore, amounted to approximately 87%.

The distillated above was neutralized with sodium hydroxide solution, concentrated on the steam-bath to 15 ml., acidified to congo red with sulfuric acid, and extracted with ether in a continuous extractor. The ether solution was dried and freed of solvent. The crystalline residue sub-limed completely at  $90-95^{\circ}$  (15 mm.). One recrystalliza-tion from Skellysolve B gave 0.55 g. (69%) of colorless feathery needles, m.p. 107°, containing nitrogen.

Anal. Calcd. for C6H11NO8: N, 9.66; neut. equiv., 145. Found: N, 9.74; neut. equiv., 145.

The substance was identified as N-isobutyloxamic acid by a mixture melting point determination with a synthetic sample, m.p. 107°.

### Summary

A pungent isobutylamide of an unsaturated C<sub>18</sub> acid has been isolated from the roots of *Heliopsis* scabra Dunal. The substance, for which the name "scabrin" is proposed, is appreciably more toxic than the pyrethrins to house flies.

Hydrogenation of the amide gave N-isobutylstearamide, and on oxidation it yielded butyric, oxalic, succinic and N-isobutyloxamic acids.

On the basis of these degradations and of its ultraviolet absorption spectrum, scabrin was shown to be the N-isobutylamide of either 2,4,8,10,14-, 2,4,8,12,14-, 2,6,8,10,14- or 2,6,10,12,14-octadecapentaenoic acid, or a mixture of these isomers.

Also isolated from the roots were two crystalline compounds, and a fluorescent oil which is also considerably toxic to house flies. These compounds will be investigated further.

# $\alpha$ -Halogenation of Secondary Nitriles<sup>1,2</sup>

BY CALVIN L. STEVENS AND T. H. COFFIELD

Recently the reaction of isobutyronitrile with phosphorus pentachloride and phosphorus pentabromide to give  $\alpha$ -chloro- and  $\alpha$ -bromoisobutyronitrile<sup>3</sup> in good yield was reported. The purpose of this paper is to extend the scope of this reaction for secondary aliphatic nitriles.

Phosphorus pentachloride has been used by Von Braun, et al.,<sup>4</sup> to  $\alpha$ -chlorinate aliphatic secondary iminochlorides in good yield at the temperature of refluxing benzene. At about 200°, phosphorus pentachloride is reported<sup>5</sup> to chlorinate  $\alpha$ -methylbutyryl chloride in unspecified yield. α-Chloroisobutyronitrile has been obtained by the direct chlorination of isobutyronitrile in sunlight.<sup>6</sup> The action of

bromine on aliphatic nitriles has been reported<sup>7</sup> to give 85–95% of bromonitriles from which the  $\alpha$ bromonitriles could not be isolated in pure form.

In this work, four aliphatic secondary nitriles (IX):  $\alpha$ -methylbutyronitrile,  $\alpha$ -ethylbutyronitrile,  $\alpha$ -ethylcapronitrile and cyclohexanecarbonitrile were chlorinated and brominated with the phosphorus pentahalides under mild conditions in the absence of solvents to give the  $\alpha$ -halonitriles (X) in 70-95% yield (see Table I, compounds I to VIII).

## $R_1R_2CHCN + PX_5 \longrightarrow R_1R_2CXCN + HX + PX_3$ $\mathbf{IX}$

Evidence that the halogen entered the  $\alpha$ -position was obtained by acid hydrolysis of the bromo- and chlorocyclohexanecarbonitrile and the bromo- and chloro- $\alpha$ -ethylbutyronitrile to give 70–95% of known amides (see Table II). Hydrolysis of the halonitriles with unsymmetrical alkyl groups gave amides that melted at or below room temperature.

<sup>a</sup> Naster and Gavriloff, Bull. soc. chim. Belg., 42, 519 (1933). <sup>b</sup> Bockmühl and Schwarz, German Patent 412,820; Chem. Centr., 96, II, 92 (1925). <sup>e</sup> Hoering and Baum, German Patent 186,739; C. A., 2, 354 (1908).

 $\alpha$ -Chloro- $\alpha$ -ethylbutyramide and  $\alpha$ -chloro- $\alpha$ -methylbutyramide were shown by independent synthesis to be identical with the amides obtained by hydrolysis of the halonitriles (X).

Further evidence for the structure of the  $\alpha$ -halonitriles was obtained by a Hofmann degradation of each of the  $\alpha$ -haloamides (XI) to the corresponding dialkyl ketone (XII) generally in 40-70% yield.

$$\begin{array}{c} R_1 R_2 CXCONH_2 + NaOBr \longrightarrow R_1 COR_2 \\ XI & XII \end{array}$$

 $\beta$ -Chloroisobutyramide and  $\beta$ -chloropropionamide were subjected to the same Hofmann degradation to determine whether a  $\beta$ -haloamide would also give a ketone or aldehyde by reactions XIII  $\rightarrow$ XV; however, no carbonyl compound was produced. With  $\beta$ -chloroisobutyramide (XVI) a 49% yield of 2-amino-1-propanol (XVII) was formed.

$$\begin{array}{c} R_1 CHCI-CHR-CONH_2 + NaOBr + NaOH \longrightarrow \\ NIII \\ R_1 CH=CR-CONH_2 \longrightarrow R_1 CH_2-CO-R \\ NIV NV \\ CH_3 \\ CICH_2-CH-CONH_2 \longrightarrow HOCH_2-CH-NH_2 \\ NVI \\ NVI \\ NVI \\ \end{array}$$

The purity of the  $\alpha$ -halonitriles (X) prepared by the halogenation reaction was proven by comparison with the product obtained by the dehydration of an authentic  $\alpha$ -haloamide with phosphorus pen-The nitriles from these two reactions were toxide. identical in all respects.

Previously, ethyl methyl ketone cyanohydrin was reported to react with phosphorus pentachloride to give  $\alpha$ -chloro- $\alpha$ -methylbutyronitrile,<sup>8</sup> but the chloronitrile was not identical with the compound prepared above. Also, hydrolysis of the chloronitrile made from the cyanohydrin gave only an oily amide. Since acetone cyanohydrin gave only  $\beta$ -chloroisobutyronitrile when treated with phosphorus pentachloride under the same conditions,3 the chloronitrile made from ethyl methyl ketone cyanohydrin also undoubtedly contained a large percentage of  $\beta$ -chloronitrile.

The reaction of phosphorus pentahalides with primary nitriles is a more complicated reaction and will be discussed later.

### Experimental

Starting Nitriles.— $\alpha$ -Methylbutyronitrile,<sup>9</sup> b.p. 123– 125°;  $n^{25}$ D 1.3885, was prepared from  $\alpha$ -methylbutyric acid via the acid chloride,<sup>10</sup> b.p. 114–115°, and the amide,<sup>10</sup> m.p. 112–113°, in 58% over-all yield.<sup>11</sup>  $\alpha$ -Ethylbutyronitrile,<sup>12</sup> b.p. 142–143°,  $n^{25}$ D 1.4001, was prepared similarly in 76% over-all yield from the acid via the acid chloride,<sup>18</sup> b.p. 137–139° and the amide,<sup>14</sup> m.p. 112– 113°.

113°

 $\alpha$ -Ethylcaproamide,<sup>15</sup> m.p. 103°, was prepared in 60% yield from the acid *via* the acid chloride,<sup>13</sup> b.p. 94–96° (31 mm.).

Dehydration of the amide using phosphorus pentoxide gave 88% of  $\alpha$ -ethylcapronitrile,<sup>16</sup> b.p. 99–100° (26 mm.);  $n^{28}$ D 1.4145. This nitrile contained 11.39% nitrogen (calcd. 11.19%).

Cyclohexanecarboxamide,<sup>17</sup> m.p. 183–185°, was prepared in 70% yield from the acid,<sup>18</sup> b.p. 108–109° (5 mm.), *via* the acid chloride,<sup>19</sup> b.p. 184–187°, or in 60% yield by hydrogenating benzamide at 1100 lb. pressure and a temperature of 100° using Raney nickel catalyst.<sup>20</sup> Dehydration of the

of 100 using heater inter-catalyst. Denymation of the amide using phosphorus pentoxide gave cyclohexanecarbo-nitrile,  $^{21}$  b.p. 187–188°,  $n^{25}$ p 1.4500, in 80% yield.  $\alpha$ -Chlorination of Secondary Nitriles.—In a 100-ml. round-bottomed flask equipped with a reflux condenser and  $\alpha$  colour chloride draing tube 0.3 mole of the secondary a calcium chloride drying tube, 0.3 mole of the secondary nitrile and an equivalent amount of phosphorus penta-chloride were mixed and heated to reflux. After about 5 hours, when the evolution of hydrogen chloride ceased, the hours, when the evolution of hydrogen change cased, the mixture was fractionated through a 15  $\times$  1.5 cm. column, packed with glass helices and equipped with a variable take-off total reflux head. The lower boiling fraction consisted of phosphorus trichloride, b.p. 74–76°, in 70–90% yield. After a small intermediate fraction, the pure  $\alpha$ -chloronitriles were isolated in 70–90% yield (see Table I).

a-Bromination of Secondary Nitriles.-Phosphorus pentabromide was made by adding one equivalent of bromine to one equivalent of cooled phosphorus tribromide. One equivalent of the secondary nitrile was added to the pentabromide and the reaction mixture heated gently at 60° for about 5 hours, during which time the reaction mixture was protected against moisture. After the hydrogen bromide ceased to be evolved, the reaction mixture was cooled and added with stirring to twice its volume of cracked ice. The organic layer was then taken up in ether, washed successively with sodium carbonate solution and water, dried over magnesium sulfate and fractionated under reduced pressure

through the 15  $\times$  1.5 cm. column described above. From 0.2 mole of nitrile, the yield of  $\alpha$ -bromonitrile was 70–90% (see Table I).

Amide Derivatives of the Halonitriles.—Derivatives of the nitriles were obtained by hydrolysis to the corresponding amides with sulfuric acid<sup>22</sup> (see Table II). One gram of the nitrile was heated with 2.0 g, of sulfuric acid and poured into cracked ice. The solid amide was filtered and recrystallized from petroleum ether. The unsymmetrically dialkylated  $\alpha$ -haloamides melted at about room temperature or below.

 $\alpha$ -Chloro- $\alpha$ -ethylbutyramide and Nitrile.—A mixture of 78 g. (0.59 mole) of  $\alpha$ -ethylbutyryl chloride and 240 g. (1.8 moles) of sulfuryl chloride were heated with 0.25 g. of iodine for 36 hours. The mixture was then distilled under reduced pressure and fractionated through a four-plate column to give 60 g. (62%) of  $\alpha$ -chloro- $\alpha$ -ethylbutyryl chloride,<sup>23</sup> b.p. 84–86° (27 mm.).

pressure and fractionated through a four-plate column to give 60 g. (62%) of  $\alpha$ -chloro- $\alpha$ -ethylbutyryl chloride,<sup>23</sup> b.p. 84-86° (27 mm.). The  $\alpha$ -chloroacid chloride (20 g., 0.15 mole) was added to 300 ml. of concentrated ammonia at 0° and the resulting amide filtered, dried and recrystallized from petroleum ether, yield 93%, m.p. 57-59°. The melting point of the mixture of this amide with the amide from  $\alpha$ -chloro- $\alpha$ -ethylbutyronitrile (III) was not depressed, m.p. 56-58°.

Instant of this time with what was a non-transferred to the purpose of the purpo

 $\alpha$ -Chloro- $\alpha$ -methylbutyramide.—This  $\alpha$ -chloroamide was prepared in the same manner as the  $\alpha$ -chloro- $\alpha$ -ethylbutyramide above. From 31.5 g. (0.26 mole) of  $\alpha$ -methylbutyryl chloride and 101 g. (0.75 mole) of sulfuryl chloride, 24.6 g. (56%) of  $\alpha$ -chloro- $\alpha$ -methylbutyryl chloride was obtained, b.p. 59-62° (37 mm.). The  $\alpha$ -chloroacid chloride (5 g., 0.03 mole) was added to concentrated ammonia and the amide filtered and recrystallized from petroleum ether, yield 95%, m.p. 36-37°. A melting point of the mixture of this amide with the amide from the  $\alpha$ -chloronitrile (I) was not depressed, m.p. 35-37°.

not depressed, m.p.  $35-37^{\circ}$ . Hofmann Degradation of  $\alpha$ -Halodialkylacetamides.—A solution of sodium hypobromite was prepared by the addition of 0.6 ml. (0.12 mole) of bromine to a solution of 2.4 g. (0.06 mole) of sodium hydroxide in 20 ml. of water at 0°. The amide (0.01 mole) was dissolved in the sodium hypobromite solution, after which the solution was heated to 70° for 20 minutes. The resulting dialkyl ketone was isolated by steam distillation of the basic reaction mixture. The water soluble ketones were separated from the distillate by salting the product from solution with potassium carbonate. The crude ketones, which were isolated generally in 40-70% yield, were identified by solid derivatives (see Table III).

### TABLE III

### HOFMANN DEGRADATION OF $\alpha$ -Haloamides

<sup>•</sup> SC (semicarbazone); NPH (p-nitrophenylhydrazone); DNPH (2,4-dinitrophenylhydrazone). Except as indicated all are common derivatives, cf. ref. 22, p. 240. <sup>b</sup> Pickard and Kenyon, J. Chem. Soc., 1936 (1913).

The Hofmann degradation of  $\beta$ -chloropropionamide,<sup>24</sup> m.p. 101-103°, and  $\beta$ -chloroisobutyramide,<sup>6</sup> m.p. 102-104°, under the same reaction conditions gave no carbonyl compounds. From 3.6 g. (0.03 mole) of  $\beta$ -chloroisobutyramide, 1.1 g. (49%) of 2-amino-1-propanol was obtained as a viscous oil and characterized by the preparation of two known derivatives, the phenylthiourea, m.p. 141.5-142°, and the chloroplatinate, m.p. 196-197°, in good yield. Reaction of Ethyl Methyl Ketone Cyanohydrin with Phos-

Reaction of Ethyl Methyl Ketone Cyanohydrin with Phosphorus Pentachloride.—Ethyl methyl ketone cyanohydrin was prepared in 60% yield and 10 g. (0.1 mole) was treated with 20 g. (0.1 mole) of phosphorus pentachloride according to the procedure of Servais.<sup>8</sup> The product was isolated in 40% yield, b.p.  $60-61^{\circ}$  (32 mm.);  $n^{25}$ D 1.4300;  $d^{25}$  0.9265. The usual hydrolysis failed to give  $\alpha$ -chloro- $\alpha$ methylbutyramide.

### Summary

1. Four dialkylacetonitriles were  $\alpha$ -halogenated at 60–100° with phosphorus pentachloride and phosphorus pentabromide to give 70–90% of the  $\alpha$ halonitriles.

2. The  $\alpha$ -halonitriles were converted in good yield to the  $\alpha$ -haloamides each of which gave a dialkyl ketone by the Hofmann degradation.
