A series of zirconocene (iv) halides, $[Zr(\eta-C_sH_4SiMe_3)_2X_2]$ [X = Cl (1) or Br (2)] and $[Zr\{\eta-C_sH_3(SiMe_3)_2-1,3\}_2X_2]$ [X = F (3), Br (4), I (5), or Cl (6)], has been prepared, either by (i) substitutive procedures from ZrCl₄ [involving the following ligand exchanges: Cl⁻/C_sH₄SiMe₃⁻, Cl⁻/C_sH₃(SiMe₃)₂⁻, Cl⁻/Br⁻, Cl⁻/I⁻, or Cl⁻/NMe₂⁻ followed by NMe₂⁻/F⁻], or (ii), for complexes (3), (5), or (6), by oxidative addition to $[Zr\{\eta-C_sH_3(SiMe_3)_2-1,3\}_2(CO)_2]$. The only $v_{asym}(ZrX_2)$ vibration to be assigned with confidence is for X = F at 563 cm⁻¹; ¹H and ¹³C n.m.r. data are unexceptional. X-Ray structure determinations of complexes (1)—(5) have been carried out. Their molecular symmetry is close to 2, or crystallographically imposed 2 in (3), with the stereochemistry about the metal centre best described as distorted tetrahedral. The angle X–Zr–X is 93.70(7), 94.2(1), 100.5(3), 100.25(5), and 100.37(4)° for the halides (1)—(5), respectively; and the corresponding centroid–Zr–centroid angles are 129.1, 128.2, 131.4, 131.4, and 131.8°. Metal–halogen distances in (1) [2.505(2) and 2.476(2) Å] and (3) [2.212(6) Å] are significantly longer than in the parent zirconocene(iv) halides [Zr(η-C_sH_s)₂X₂] (cf. 2.44 Å for X = Cl and 1.98 Å for X = F) as are [by ca. 0.04 Å (average)] the metal–centroid distances in (3)—(5).

Part 3¹ of the present series dealt with the synthesis, structure, and dynamic behaviour of d^0 zirconocene(IV) complexes of formula [Zr(η -C₅H₄R)₂ClR'] [R = alkyl or SiMe₃, R' = CH(SiMe₃)₂]. The synthesis of the precursors to such complexes, viz. [Zr(η -C₅H₄R)₂Cl₂], was described in Part 2.² Herein we further develop zirconocene dihalide chemistry for the case of the cyclopentadienyl ligands possessing one or two of the bulky lipophilic substituents SiMe₃, viz. [Zr(η -C₅H₄-SiMe₃)₂X₂] (X = halide) and [Zr{ η -C₅H₃(SiMe₃)₂-1,3}₂X₂].

The ligand η -C₅H₃(SiMe₃)₂-1,3 is relatively new and has featured in some unusual chemistry, *e.g.*, (i) the deoxygenation of CO₂ upon reduction of [Zr{ η -C₅H₃(SiMe₃)₂-1,3}₂Cl₂], the zirconocene product being [Zr{ η -C₅H₃(SiMe₃)₂-1,3}₂(CO)₂];³ (ii) the formation of the first metallocene(III) chlorides of the early lanthanoids, [{Ln[η -C₅H₃(SiMe₃)₂-1,3]₂(μ -Cl)}₂]⁴ and [Ln{ η -C₅H₃(SiMe₃)₂-1,3]₂Cl₂]⁻⁵ (iii) novel uranocene(III) halides [{U[η -C₅H₃(SiMe₃)₂-1,3]₂(μ -Xl)_n] (X = F, Cl, Br, or I; *n* = 2 in the crystal, at least for X = Cl or Br);⁶ and (iv) the first tris(η -cyclopentadienyl)metal complex, [Th{ η -C₅-H₃(SiMe₃)₂-1,3}₃].⁷ These results presumably relate to the steric hindrance around the metal centres from the large ring substituents coupled with the orientation of the two η -C₅H₃(SiMe₃)₂-1,3 ligands relative to one another. We have drawn attention to the similarity but also complementarity of this ligand with the much studied η -C₅Me₅;⁴ however, it

‡ No reprints available.

appears that η -C₅H₃(SiMe₃)₂-1,3 is sterically the more demanding as evident, for example, from the existence in the crystal of [{U[η -C₅H₃(SiMe₃)₂-1,3]₂(μ -Cl)}₂],⁶ but [{U(η -C₅Me₅)₂(μ -Cl)}₃].⁸

In order to study further the effect on the metal environment of incorporating either one or two SiMe₃ groups in each of the cyclopentadienyl ligands, we have undertaken X-ray structure determinations on several silylated zirconocene dihalides, viz. $[Zr(\eta-C_5H_4SiMe_3)_2X_2]$ [X = Cl (1), or Br (2)] and $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2X_2]$ [X = F (3), Br (4), or I (5)]. We had hoped to provide such data also for $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2Cl_2]$ (6), which together with (1) would have permitted more detailed comparisons to be made with the parent compound $[Zr(\eta-C_5H_5)_2Cl_2]$. However, crystals of (6) were found to be unsatisfactory.

In a subsequent paper we shall present electrochemical data on the one-electron reduction of a series of d^0 complexes of formula [M(η -C₅H₃R¹R²)₂X₂][M = Ti, Zr, or Hf; R¹R² = H₂, H(SiMe₃), or (SiMe₃)₂-1,3; X = F, Cl, Br, or I], and e.s.r. results on the derived M^{III} d^1 complexes. This will provide a further probe into the stereo-electronic effects associated with progressive SiMe₃ substitution in the cyclopentadienyl rings. We are also exploring the role of η -C₅H₂(SiMe₃)₃-1,2,4 in this and related areas of chemistry.

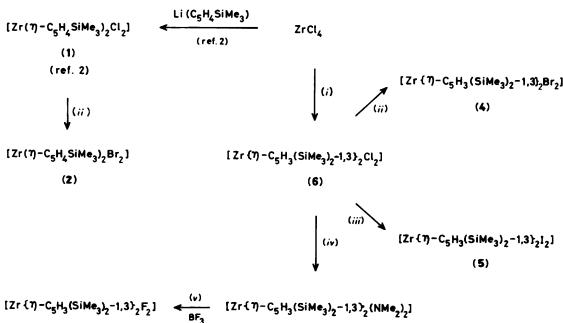

Results and Discussion

The syntheses of the zirconocene(IV) halides (1)—(6) are outlined in Schemes 1 (from Zr^{IV} precursors) and 2 (from a Zr^{II} carbonyl). The general methods, which, in principle, are now well established ^{9,10} (reference to the first use of each general procedure is given in parentheses), involved (i) $Cl^{-}/C_{5}H_{4}$ -SiMe₃⁻ or $Cl^{-}/C_{5}H_{3}(SiMe_{3})_{2}^{-}$ exchange (ref. 11), (ii) Cl^{-}/F^{-} exchange (via the NMe₂⁻ derivative ¹²), (iii) Cl^{-}/X^{-} (X = Br or

 $[\]dagger$ Bis(η -trimethylsilylcyclopentadienyl)-dichlorozirconium(iv) and -dibromozirconium(iv); bis[η -1,3-bis(trimethylsilyl)cyclopentadienyl)]difluorozirconium(iv), -dibromozirconium(iv), and -di-iodozirconium-(iv) respectively.

"Yields refer to purified compounds and relate to the methods of Scheme 1 (or Scheme 2, in parentheses). Based on $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2Cl_2]$. Not recorded. From $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(CO)_2] + I_2$.

 I^{12}), or (iv) oxidative addition (via Ag[BF₄], PhCH₂Cl, MeI, or I_2^{3}). The substitution reactions shown in Scheme 1 were perceptibly slower than those for the corresponding C_5H_5 systems,^{11,12} no doubt due to the greater steric hindrance associated with the SiMe₃-substituted ligands. The Ag[BF₄]

experiment was designed to provide a Zr^{III} cationic complex. A Zr^{III} species was detected, but it decayed slowly at ambient temperature; compound (3) was identified among the products, but this is not a viable synthetic route.

In Table 1 we summarise the yields, melting points,

1465

microanalyses, and appearance of the compounds. The reported yields represent the cumulative total of two, or sometimes three, successive low-temperature crystallisations from the mother-liquor, made necessary by the high solubility of the compounds in hydrocarbons (a feature associated with the lipophilic SiMe₃ groups).

assignments. The ¹⁹F chemical shift recorded for (3) appears to be the first for a diamagnetic metallocene(1v) difluoride, cf. the $f^2 \text{ complex} [\{U(\mu-BF_4)[\eta-C_5H_3(SiMe_3)_2-1,3]_2(\mu-F)\}_2]^{13}$

The i.r. spectra for the complexes (3)–(5) were virtually identical to one another. The majority of the bands are associated with vibrations of the η -C₅H₃(SiMe₃)₂-1,3 ligand, which appear at slightly higher wavenumber than analogous modes found in [Zr(η -C₅H₅)₂X₂].¹² The only metal-halogen

The ¹H, ¹³C, and, for (3), the ¹⁹F n.m.r. data on the zirconocene(iv) halides are presented in Table 2, together with

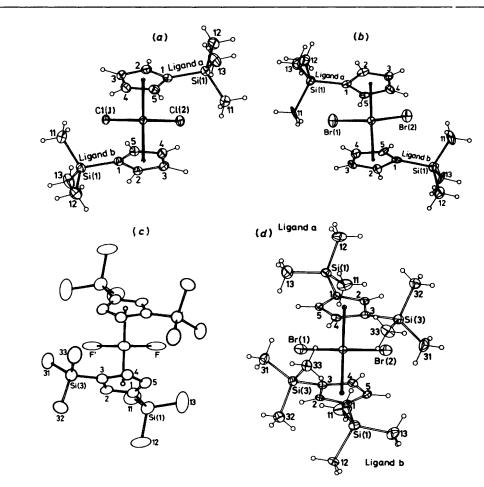

Figure 1. Molecular projections down the X-Zr-X bisector for (a) (1), (b) (2), (c) (3), and (d) (4): 20% thermal ellipsoids are shown for the nonhydrogen atoms; hydrogen atoms have an arbitrary radius of 0.1 Å [except (3)]. Complex (5) is isostructural with (4) and therefore has the same orientation of ligands

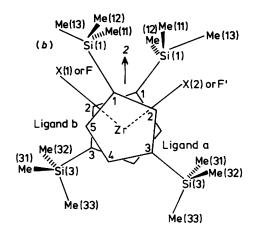

Figure 2. Diagrammatic representation of the structures of (a) (1) and (2), (b) (3)–(5), in projection down the line through the C_5 ring centroids. In (3), ligands a and b, and X(1) and X(2), are related by a crystallographic 2 symmetry axis

stretching mode to be definitively identified was $v_{asym}(ZrF_2)$ at 563 cm⁻¹ (Nujol mull) in (3), cf. 528 cm⁻¹ in $[Zr(\eta-C_5H_5)_2F_2]$.¹⁴

Single-crystal X-ray structure determinations of complexes (1)-(5) showed that in each case the unit-cell contents comprised discrete molecules of the expected stoicheiometry $[Zr(\eta - C_5H_3R^1R^2)_2X_2][X = F, Cl, Br, or I; R^1R^2 = H(SiMe_3)$ or $(SiMe_3)_2$ -1,3], Figure 1. The asymmetric unit was a single molecule, except for (3) in which it was half a molecule, the other half being generated by a two-fold rotor. The stereochemistry about the zirconium atom was invariably that found in previously studied bent sandwich complexes of the type $[ML_2X_2]$ (M = Zr or Hf, L = η -cyclopentadienyl or an analogue),¹⁰ conveniently described as a distorted tetrahedron by considering the ligand L⁻ as a sterically demanding unidentate moiety. For (2), (4), and (5), the space group of the structure was found to be chiral. The parent compounds [$Zr(\eta$ - $C_{5}H_{5}\lambda_{2}$ may have either an 'eclipsed' or a 'staggered' conformation (as assessed by projection of the pair of ring systems down the line through their centroids); thus, the highest molecular point symmetry is either mm or m. The introduction of a single substituent in each cyclopentadienyl ring usually has the effect of removing the mirror planes, limiting the maximum point symmetry of the substituted molecule to 2; consequently, in the absence of a suitable scrambling mechanism, a molecule $[Zr(\eta-C_5H_4R)_2X_2]$ could be optically active. Given the

observed space groups of (2) $(P2_1)$, (4) $(P2_12_12_1)$, and (5) $(P2_12_12_1)$, the growth of substantial crystals could therefore provide a possible starting point for stereospecific synthesis, using the solid state as a suitable orientating medium.

The ligand substituents are opposite each other in the η -C₅H₄SiMe₃ complexes (1) and (2), Figure 2(*a*), in contrast with their being eclipsed in [Zr{(η -C₅H₄CH₂)₂CH₂}Cl₂],¹⁵ where the pentahapto ligands are linked, and in [Zr(η -C₅H₄CH₂-Ph)₂Cl₂] (I).¹⁶ Although complexes (1) and (2), like (I), are monosubstituted zirconocene(1v) dihalides, their different conformation [*cf*. (I) and Figure 2(*a*)] is ascribed to the larger steric requirements of the SiMe₃ substituents. Thus for (1) or (2), unfavourable non-bonding interactions would result if the SiMe₃ substituents were eclipsed and astride the two halides. In the η -C₅H₃(SiMe₃)₂-1,3 complexes (3)—(5), a set of

substituents lies close to those (R) found in (I), but with the rings staggered, Figure 2(b).

The X-ray parameters are summarised as follows: nonhydrogen atom co-ordinates in Tables 3 [(1) and (2)], 4 [(3)], and 5 [(4) and (5)]; selected metal atom geometries in Table 6; and ligand planes in Table 7. Some of the key molecular parameters now reported for complexes (1)—(5) are placed in the context of relevant literature data in Table 8.

The binding of the rings in each of the structures of complexes (1)—(5) is slightly unsymmetrical; the substituted carbon atoms and nearest ring neighbours are the furthest from the metal centre, by up to 0.08 Å relative to the others. Interestingly, in (I) this effect is somewhat more pronounced (maximum difference 0.13 Å),¹⁶ while in $[ZrCl_2(C_{13}H_9)_2]$ it is so great that the bonding of one fluorenyl group $(C_{13}H_9)$ is best described as

approaching an η^3 interaction (Table 8).¹⁷ The departure from symmetrical binding in complexes (1)—(5), and also in (I) and in [Zr{CH(SiMe_3)₂}(η -C₅H₄R)₂Cl] (R = Bu^t or SiMe₃),¹ relates to the substituents being forced to reside out of the ligand planes, away from the metal centre, as a consequence of steric effects.¹ The central atom of the ring substituents lies close to 0.3 Å out of the C₅ ring plane (Table 7) except in the fluoride (3) where it is less, possibly due to lower crowding around the metal by the smaller halides.

In each of the structures of complexes (1)—(5), one of the SiMe₃ methyl groups is disposed pseudo-coplanar with the ligand C₅ plane [C(mn3)], one lies out-of-plane on the side of the zirconium by rather less than 1 Å [C(mn1)], while the third [C(mn2)] is located out-of-plane on the side opposite the zirconium by ca. 2 Å (Table 7). The overall substituent disposition is, in fact, a good approximation in (1), (2), (4), and (5) to the ideal 2 symmetry postulated above, with a suitably snug disposition of close substituent-ligand contacts within each molecule. There is no systematic asymmetry in the exocyclic angles at the points of attachment of the silicon atoms.

While the centroid-Zr-centroid angle in each of the η -C₅H₄SiMe₃ complexes (1) and (2) differs substantially from that of the appropriate parent compound [Zr(η -C₅H₅)₂X₂] (X = F,¹⁸ Cl,¹⁹ or I¹⁸), the more reliable X-Zr-X angle differs only marginally (Table 8) in a direction consistent with mutual repulsion of the ring SiMe₃ substituents and the halide ligands, see Figure 2(*a*). For (I), the X-Zr-X angle is similar to that found in (1) and (2), but in (I) such repulsion would operate in the opposite direction and would be minimal because of the

smaller size of the benzyl substituents in the C_5 rings and of the chloride ligands.

The effect of changing the halide for the system $[Zr{n C_5H_3(SiMe_3)_2-1,3_2X_2$ is small, as was also found ^{18.19} for the parent compounds $[Zr(\eta-C_5H_5)_2X_2]$. For each of the complexes (3)-(5), both the centroid-Zr-centroid and X-Zr-X angles are remarkably similar; the X-Zr-X angle is larger by ca. 3° than in $[Zr(\eta-C_5H_5)_2X_2]$, the converse trend from that observed for the η -C₅H₄SiMe₃ complexes (1) or (2). It is noteworthy that two of the SiMe, substituents project within the X-Zr-X angle, but are not eclipsed as in (I); the SiMe₃halide repulsions associated with these particular SiMe₃ groups would tend to favour an increase in the X-Zr-X angle at the expense of repulsions between the other $SiMe_3$ groups and X⁻. The centroid-Zr-centroid angle is uniformly larger in complexes (3)—(5) than in (1) or (2) (consistent with the disilylated ligand being more sterically demanding), as is the increase in average metal-carbon distance, Table 8. Interestingly, the neodymate ion $[Nd{\eta-C_5H_3(SiMe_3)_2-1,3}_2Cl_2]^-$ has structural angular parameters (see above) defining the distorted tetrahedral co-ordination sphere of the metal,⁵ which are similar to those of the isoleptic complexes (3)-(5).

The Zr–Cl distances in (1), 2.505(2) and 2.476(2) Å, are longer than those of the parent compound $[Zr(\eta-C_5H_5)_2Cl_2]$,¹⁹ and are the longest Zr–Cl distances yet recorded for a zirconocene chloride.¹⁰ [Unfortunately data on (6), the η -C₅H₃(SiMe₃)₂-1,3 analogue of (1), are not available, but it is likely that complex (6) would have even longer Zr–Cl bonds.] For the di-iodide (5), however, no change in the Zr–X distance relative to the parent

compound ¹⁸ was evident (Table 8); this is likely therefore also to be the case for the as yet unknown intermediate compound $[Zr(\eta-C_5H_4SiMe_3)_2I_2]$. In the two bromides (2) and (4), the Zr-Br distances are similar. A surprising result is the exceptionally long Zr-F distance in (3), 2.212(6) Å, compared to that ¹⁸ in $[Zr(\eta-C_5H_5)_2F_2]$, 1.98(1) Å. Thus, for zirconocene fluorides, and to a lesser extent chlorides, there is an increase in metal-halide distance with increase in trimethylsilyl substitution of the rings. In the case of (6) this is reflected in its chemistry by the greater ease of displacement of the chloride ligands than in η - $C_5H_4SiMe_3$ or η - C_5H_5 analogues, *e.g.*, in the reductive carbonylation to yield $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(CO)_2]$.³

Experimental

General procedures have been described in Parts 1²⁰ and 2.²

Synthesis of $[Zr(\eta-C_5H_4SiMe_3)_2Cl_2]$ (1).—Compound (1) was prepared using a modification of the literature method.² Trimethylsilylcyclopentadiene (20.0 g, 145 mmol) was added to a mixture of sodium sand (3.0 g, 130 mmol) and tetrahydrofuran (thf, 100 cm³). A white precipitate formed over several days; when no sodium remained (*ca.* 5 d), the stirred suspension was cooled (0 °C) and freshly sublimed zirconium(IV) chloride (15.2 g, 65 mmol) was added slowly over 0.5 h. The mixture was then stirred at 20 °C for 2 h. Removal of thf *in vacuo*, followed by extraction with boiling hexane (200 cm³), filtration, concentration of the filtrate (to *ca.* 100 cm³), and cooling to -30 °C gave colourless needles of complex (1) (14.0 g, 50%), m.p. 130— 131 °C (lit.² 130—133 °C).

Synthesis of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2F_2]$ (3).—(a) Boron trifluoride-diethyl ether (0.33 g, 2.3 mmol) was added at 0 °C to a solution of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(NMe_2)_2]^{21}$ (1.31 g, 2.3 mmol) in benzene (20 cm³). After stirring for 30 min, the colour of the supernatant liquor had changed from orange-yellow to colourless and a white precipitate had formed. Stirring was continued for *ca.* 2 h, whereafter volatiles were removed *in vacuo*. Sublimation of the solid residue yielded dimethyl-

amidoboron difluoride (sublimes at $80 \,^{\circ}\text{C}/10^{-2}$ Torr). The involatile residual solid was extracted into toluene (25 cm³); the extract was filtered and the filtrate concentrated. Cooling the latter overnight to $-30 \,^{\circ}\text{C}$ produced colourless crystals of the complex (3) (1.02 g, 81%), which were washed with cold pentane and dried *in vacuo*.

(b) Silver tetrafluoroborate (0.4 g, 2.27 mmol) was added to a solution of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(CO)_2]$ (1.5 g, 2.27 mmol) in thf (40 cm³) at -30 °C. A copious precipitate was instantly formed. The mixture became brown and was slowly brought to 25 °C. The e.s.r. spectrum showed that a Zr^{III} species had formed (see Scheme 2). This paramagnetic material slowly decayed during *ca*. 4 h. From the filtrate, (3) was obtained and characterised by comparison with the material obtained from (*a*).

Synthesis of $[Zr(\eta-C_5H_4SiMe_3)_2Br_2]$ (2).—Boron tribromide (1 cm³, 10 mmol) in dichloromethane (15 cm³) was added to a stirred solution of (1) (1.0 g, 2 mmol) in CH₂Cl₂ (15 cm³). Stirring was continued for 1 h, and volatiles were removed *in* vacuo. The residue was extracted into toluene (25 cm³). The filtrate, upon concentration and cooling to -30 °C, gave pale green crystals of *complex* (2) (0.9 g, 75%), which were washed with pentane and dried *in vacuo*.

Synthesis of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2Cl_2]$ (6).—(a) This compound was prepared using a modification of the literature method.²² n-Butyl-lithium (23 cm³ of a 1.6 mol dm⁻³ solution in hexane, 36 mmol) was added to a stirred solution of bis-(trimethylsilyl)cyclopentadiene (7.5 g, 30 mmol) in thf (100 cm³). After stirring overnight, the solution was cooled to 0 °C and freshly sublimed zirconium(Iv) chloride (4.15 g, 18 mmol) was added in portions over 1 h. The reaction mixture was again stirred overnight, whereafter it had become golden yellow. Solvent was removed *in vacuo* and the resulting yellow solid was dissolved in hot toluene (100 cm³), activated charcoal was added, and the hot mixture was filtered. The yellow filtrate was concentrated and cooled to -30 °C to give white crystals of complex (6) (8.0 g, 77%), m.p. 180—182 °C (lit.,²² 180—181 °C). (b) This experiment was not carried out in a quantitative manner. Excess of benzyl chloride was added to $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(CO)_2]$ (ca. 1 g) in n-hexane (25 cm³). The solution was irradiated for 3 h at 25 °C using a medium-pressure mercury lamp, whereafter (6) was isolated as a precipitate by concentration and cooling (-30 °C).

Synthesis of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2Br_2]$ (4).—Boron tribromide (2.9 g, 11 mmol) in dichloromethane (10 cm³) was added to a stirred solution of (6) (6.2 g, 11 mmol) in the same solvent (20 cm³). Stirring was continued for 1 h, whereafter volatiles were removed *in vacuo*. The residue was extracted into pentane (20 cm³) and, after filtration and concentration, the filtrate upon cooling to -30 °C gave pale green crystals of the *complex* (4) (6.0 g, 92%), which were washed with cold pentane and dried *in vacuo*.

Synthesis of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2I_2]$ (5).—(a) Boron tri-iodide (3.50 g, 8.95 mmol) in CH_2Cl_2 (35 cm³) was added to a stirred solution of $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2Cl_2]$ (6) (5.18 g, 8.92 mmol) in dichloromethane (30 cm³) during ca. 10 min at 20 °C. The initially colourless solution became deep pink and after stirring for ca. 1 h had developed a deep orange colour. Stirring was continued for ca. 5 h, whereafter volatiles were removed *in vacuo*. The solid residue was extracted into hexane (40 cm³). The extract was filtered and the filtrate concentrated and cooled to ca. -30 °C to yield a yellow powder, which was recrystallised twice in the same manner to afford bright yellow crystals of the complex (5) (6.40 g, 94%), which were dried *in vacuo*.

(b) The procedure was identical to that described for the $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2(CO)_2]$ -PhCH₂Cl system, except that MeI was used in place of PhCH₂Cl, giving yellow crystals of (5).

(c) A solution of di-iodine (0.45 g, 1.77 mmol) in diethyl ether (10 cm³) was added slowly to $[Zr{\eta-C_5H_3(SiMe_3)_2-1,3}_2-(CO)_2]$ (1.0 g, 1.77 mmol) in the same solvent (10 cm³) at 25 °C. Gas evolution was observed, and the solution became yellow. Cooling to -30 °C afforded yellow crystals of complex (5) (1.23 g, 91%), m.p. 185 °C.

X-Ray Data Collection, Structure Solution, and Refinement for (1)—(5).—Crystal data for (1). $C_{16}H_{26}Cl_2Si_2Zr$, M = 436.7, triclinic, space group PI (C_i^1 , no. 2), a = 13.051(7), b = 13.054(6), c = 6.859(4) Å, $\alpha = 97.72(4)$, $\beta = 106.17(4)$, $\gamma = 107.43(4)^\circ$, U = 1.040.0(9) Å³, $D_c = 1.39$ g cm⁻³ (Z = 2), F(000) = 448, $\mu_{Mo} = 8.8$ cm⁻¹. Specimen: irregular wedge, ca. 0.5 mm (capillary), $2\theta_{max.} = 50^\circ$, N = 3.660, $N_o = 3.080$, R = 0.049, R' = 0.085.

Crystal data for (2). $C_{16}H_{26}Br_2Si_2Zr$, M = 525.5, monoclinic, space group $P2_1$ (C_2^2 , no. 4), a = 6.958(7), b = 13.436(13), c = 11.298(11) Å, $\beta = 91.56(8)^\circ$, U = 1.056(2) Å³, $D_c = 1.65$ g cm⁻³ (Z = 2), F(000) = 520, $\mu_{Mo} = 46.2$ cm⁻¹. Specimen: $0.4 \times 0.1 \times 0.05$ mm (capillary), $2\theta_{max} = 45^\circ$, N = 1.472, $N_o = 907$, R = 0.044, R' = 0.047 (preferred chirality).

Crystal data for (3). $C_{22}H_{42}F_{2}Si_{4}Zr$, M = 548.1, orthorhombic, space group *Pbcn* $(D_{2h}^{-14}, \text{ no. 60})$, a = 18.356(8), b = 8.888(4), c = 18.620(7) Å, U = 3.038(2) Å³, $D_c = 1.198$ g cm⁻³ (Z = 4), F(000) = 1.152, $\mu_{Mo} = 4.84$ cm⁻¹. Specimen: $0.2 \times 0.2 \times 0.3$ mm (capillary), $2\theta_{max.} = 50^{\circ}$, N = 2.701, $N_o = 1.368$, R = 0.060, R' = 0.073.

Crystal data for (4). $C_{22}H_{42}Br_2Si_4Zr$, M = 669.9, orthorhombic, space group $P2_12_12_1$ (D_2^4 , no. 19), a = 18.041(5), b = 16.244(4), c = 10.703(3) Å, U = 3 137(1) Å³, $D_c = 1.42$ g cm⁻³ (Z = 4), F(000) = 1 360, $\mu_{Mo} = 32.0$ cm⁻¹. Specimen: $0.2 \times 0.2 \times 0.4$ mm (capillary), $2\theta_{max} = 45^\circ$, N = 2 262, $N_o = 1$ 824, R = 0.031, R' = 0.038 (preferred chirality).

Crystal data for (5). $C_{22}H_{42}I_2Si_4Zr$, M = 763.9, orthorhom-

1471

bic, space group $P2_12_12_1$, a = 18.075(4), b = 16.319(3), c = 10.844(2) Å, U = 3199(1) Å, $D_c = 1.59$ g cm⁻³ (Z = 4), F(000) = 1504, $\mu_{Mo} = 24.4$ cm⁻¹. Specimen: $0.28 \times 0.18 \times 0.45$ mm, $2\theta_{max.} = 50^{\circ}$, N = 2400, $N_o = 2075$, R = 0.032, R' = 0.020 [preferred chirality the reverse of (4); co-ordinate setting (1 - x, 1 - y, 1 - z)].

Structure determination. Unique data sets were measured within the specified $2\theta_{max}$ limits using a Syntex $P2_1$ four-circle diffractometer in a conventional $2\theta/\theta$ scan mode; T was 295 K and a monochromatic Mo- K_{α} radiation source was used ($\lambda =$ 0.710 6₉ Å). N Independent reflections were obtained, N_0 with $I > 3\sigma(I)$ being considered 'observed' and used in the 9 \times 9 block diagonal [except (3): full matrix] least-squares refinement after analytical absorption correction [except (1) and (3)] and solution of each structure by the heavy-atom method. Anisotropic thermal parameters were refined for the nonhydrogen atoms; (x, y, z, U_{iso}) H [except (3)] constrained to reasonable values and U_{iso} values taken as equal to those of the atoms to which each H is attached. The quality of the X-ray data for (3) did not justify inclusion of the hydrogen atom positions; the most significant electron residuals were located in the vicinity of the fluorine atom (0.75 e $Å^{-3}$) compared with 0.45 e Å⁻³ for cyclopentadienyl hydrogens. Reflection weights were $[\sigma^2(F_0) + 0.0005(F_0)^2]^{-1}$, or for (3) $[3.24 - 0.0128|F_0]$ + 0.000 $39|F_0|^2$]⁻¹. Neutral atom scattering factors were used, those for the non-hydrogen atoms being corrected for anomalous dispersion (f', f'').²³ Computation used the X-RAY 76 program system²⁴ implemented on a Perkin-Elmer 3240 computer by S. R. Hall [except (3), for which computer programs are described elsewhere 257.

Acknowledgements

We gratefully acknowledge support from the S.E.R.C. (CASE studentship for D. J. W. W., and fellowship for A. S.), I.C.I. Plastics Division (for D. J. W. W.), the Australian Research Grant Scheme, and the National Science and Engineering Research Council of Canada, and Drs. J. McMeeking and J. A. Segal for their interest.
