

# Photolysis of Tetrafluorohydrazine and Thiocarbonyl Chloride. Preparation of Dichlorodifluoraminomethanesulfenyl Chloride and Some Polyhalodifluoraminomethanes<sup>1</sup>

L. M. Zaborowski and Jean'ne M. Shreeve

Contribution from the Department of Chemistry, University of Idaho, Moscow, Idaho 83843. Received December 15, 1969

**Abstract:** Photolysis of  $\text{N}_2\text{F}_4$  and  $\text{CSCl}_2$  produces a variety of products, including  $\text{NF}_2\text{Cl}_2\text{CSCl}$ ,  $\text{NF}_2\text{CCl}_3$ , and  $\text{NF}_2\text{-CFCl}_2$ . The yields of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  and  $\text{NF}_2\text{CCl}_3$  are strongly influenced by reaction conditions.  $\text{NF}_2\text{CF}_3$  can be prepared in good yield by the photolytic reaction of  $\text{N}_2\text{F}_4$  with  $(\text{CF}_3)_2\text{CO}$ . Excess  $\text{KF}$  with  $\text{NF}_2\text{Cl}_2\text{CSCl}$  leads unexpectedly to  $\text{CF}_3\text{N}=\text{SF}_2$ . Thermolysis of  $\text{NF}_2\text{CFCl}_2$  and mercury gives *syn*- and *anti*- $\text{FN}=\text{CFCl}$ .

Photolysis reactions of tetrafluorohydrazine and a large number of aromatic hydrocarbons and olefins as well as acetylene lead to saturation by addition of the difluoramin radical.<sup>2</sup> Since other unsaturated systems are likely to behave in an analogous manner, thiophosgene ( $\text{CSCl}_2$ ) was selected for study based on the reactivity of the  $>\text{C}=\text{S}$  group in the presence of ultraviolet light, which catalyzes the dimerization of  $\text{CSCl}_2$  to a white, nonvolatile solid (eq 1).<sup>3</sup>

A number of products result from irradiating  $\text{N}_2\text{F}_4$  and  $\text{CSCl}_2$ , including the new sulfur(II) compound dichlorodifluoraminomethanesulfenyl chloride,  $\text{NF}_2\text{-Cl}_2\text{CSCl}$ . Two other compounds synthesized during this study, trichlorodifluoraminomethane,  $\text{NF}_2\text{CCl}_3$ , and dichlorodifluoraminomethane,  $\text{NF}_2\text{CFCl}_2$ , were revealed while this work was underway.<sup>4a</sup> We have further characterized these new compounds.

## Experimental Section

**Starting Materials.** Thiophosgene (Pfaltz and Bauer, Inc.) was purified by a trap-to-trap distillation. Anhydrous  $\text{KF}$  was prepared from  $\text{KF} \cdot 2\text{H}_2\text{O}$  by dehydrating the salt at  $200^\circ$  for 12 hr in a vacuum oven. Tetrafluorohydrazine (Air Products Co.) and hexafluoroacetone (Pierce Chemicals) were used without further purification.

**Caution!** Care should be exercised in handling tetrafluorohydrazine since nitrogen-halogen compounds are known to exhibit explosive properties. Any apparatus used should be clean and free of organic materials.

**General Procedures.** Gases and volatile liquids were handled in a conventional Pyrex vacuum apparatus equipped with a Wallace

and Tiernan mechanical gauge. Gaseous starting materials and purified products were measured quantitatively by *PVT* techniques. Photolysis reactions were carried out in a 5-l. Pyrex vessel equipped with a water-cooled quartz probe. For gas chromatographic separations the columns were constructed of 0.25-in. aluminum or copper tubing packed with 20% Kel-F-3 polymer oil (3M Co.) on acid-washed Chromosorb P. In some cases, fractional condensation was used to effect crude separation. Molecular weight measurements were carried out by vapor density techniques with a Pyrex weighing vessel.

Infrared spectra were recorded with a Beckman IR-5A or Perkin-Elmer 621 spectrophotometer by using a 5-cm gas cell equipped with KBr windows or a 10-cm gas cell with AgCl windows. Fluorine-19 nmr spectra were obtained on a Varian HA-100 spectrometer. Mass spectra were obtained with a Perkin-Elmer Hitachi RMU-6E mass spectrometer at an ionization potential of 70 eV. The ultraviolet light source was a 450-W lamp equipped with a Vycor or Correx filter (Hanovia L-679A36, Engelhard Hanovia, Inc., Engelhard, N. J.).

**Preparation of  $\text{NF}_2\text{Cl}_2\text{CSCl}$ ,  $\text{NF}_2\text{CCl}_3$ , and  $\text{NF}_2\text{CFCl}_2$ .**  $\text{N}_2\text{F}_4$  and  $\text{CSCl}_2$  were photolyzed under a variety of conditions (Table I) resulting in various yields of the desired compounds. Other products found in these reactions included  $\text{N}_2$ , *cis*- $\text{N}_2\text{F}_2$ ,  $\text{NF}_2\text{Cl}$ ,  $\text{SiF}_4$ ,  $(\text{NO})_2$ ,  $\text{SiF}_6$ ,  $\text{SO}_2$ ,  $\text{SOF}_2$ ,  $\text{S}$ ,  $\text{CF}_4$ ,  $\text{CF}_3\text{Cl}$ ,  $\text{CF}_2\text{Cl}_2$ ,  $\text{CFCl}_3$ ,  $\text{CCl}_4$ ,  $\text{Cl}_3\text{CSCl}$ ,  $\text{CS}_2$ ,  $\text{Cl}_2$ ,  $\text{COS}$ , and  $\text{C}_2\text{S}_2\text{Cl}_4$ . A crude separation resulted from passing the photolysis products through a series of traps at  $-47^\circ$ ,  $-78^\circ$ ,  $-120^\circ$ , and  $-195^\circ$ . Each trap contained a mixture of products with  $\text{NF}_2\text{Cl}_2\text{CSCl}$  stopping at  $-47^\circ$ ,  $\text{NF}_2\text{CCl}_3$  at  $-78^\circ$ , and  $\text{NF}_2\text{-CFCl}_2$  at  $-120^\circ$ . Pure  $\text{NF}_2\text{Cl}_2\text{CSCl}$  was obtained by gas chromatography with a 3-ft Kel-F-3 column;  $\text{NF}_2\text{CCl}_3$  required a 7-ft column, and  $\text{NF}_2\text{CFCl}_2$  a 24-ft column.

**Properties of  $\text{NF}_2\text{Cl}_2\text{CSCl}$ .** Dichlorodifluoraminomethanesulfenyl chloride is a light yellow liquid at room temperature with an odor similar to that of  $\text{Cl}_3\text{CSCl}$ . It has a vapor pressure of 8 mm at room temperature and reacts slowly with glass but rapidly with mercury. For these reasons a vapor pressure study was not attempted.  $\text{NF}_2\text{Cl}_2\text{CSCl}$  gives a single broad peak in the  $^{19}\text{F}$  nmr at  $\phi -49.9$  ( $\text{CCl}_3\text{F}$  internal standard). The infrared spectrum (8 mm of pressure in a 10-cm cell with AgCl windows) is ( $\text{cm}^{-1}$ ): 1013 (m), 923 (m), 895 (s), 873 (s), 844 (s), 775 (w), 628 (m), 541 (m). The principal peaks in the mass spectrum corresponded to the ions  $\text{S}^+$ ,  $\text{Cl}^+$ ,  $\text{CS}^+$  (100%),  $\text{ClCN}^+$ ,  $\text{F}_2\text{NC}^+$ ,  $\text{SCl}^+$ ,  $\text{ClCS}^+$ ,  $\text{FNCCl}^+$ ,  $\text{NCCl}_2^+$ ,  $\text{F}_2\text{NCCl}^+$ ,  $\text{Cl}_2\text{CS}^+$ ,  $\text{FNCCl}_2^+$ ,  $\text{F}_2\text{NClCS}^+$ ,  $\text{F}_2\text{NCCl}_2^+$ ,  $\text{FNCl}_2\text{-CS}^+$ ,  $\text{Cl}_2\text{CSCl}^+$ ,  $\text{F}_2\text{NCl}_2\text{CS}^+$ . Parent peaks ( $\text{F}_2\text{NCl}_2\text{CSCl}^+$ ), although very weak, were noted at mass numbers 201, 203, 205, and 207.  $\text{NF}_2\text{Cl}_2\text{CSCl}$  also gave a  $\text{SiF}_3^+$  peak resulting from attack on the glass inlet system of the mass spectrometer. All chlorine-containing fragments gave the correct isotopic peaks and relative intensities. Basic hydrolysis of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  was used to obtain aqueous solutions for elemental analysis.  $\text{H}_2\text{O}_2$  was added to the hydrolysis products to oxidize sulfide to sulfate. Fluorine was determined using a specific ion electrode (Orion Research, Inc., Model 94-09). Sulfur and chlorine were both determined gravimetrically as barium sulfate and silver chloride, respectively.

**Anal.** Calcd for  $\text{NF}_2\text{Cl}_2\text{CSCl}$ : S, 15.84; Cl, 52.54; F, 18.75. Found: S, 15.24; Cl, 52.30; F, 18.46.

**$\text{NF}_2\text{Cl}_2\text{CSCl} + \text{KF}$ .** Anhydrous  $\text{KF}$  was pretreated with hexafluoroacetone (with acetonitrile as solvent) to form the adduct  $\text{KOCF}(\text{CF}_3)_2$  which was thermally decomposed to finely divided

KF and  $(\text{CF}_3)_2\text{CO}$ .  $\text{NF}_2\text{Cl}_2\text{CSCl}$  (0.61 g, 0.003 mol) and excess KF were allowed to react at room temperature in a 30-ml metal bomb for three days. The volatile products were separated on a 24-ft Kel-F-3 column and the major component was found to be trifluoromethyliminosulfur difluoride (>70% yield).  $\text{CF}_3\text{N}=\text{SF}_2$  was identified by its infrared spectrum,<sup>5</sup> mass spectrum,<sup>6</sup> molecular weight (calcd, 153.08; found, 152.7), and  $^{19}\text{F}$  nmr ( $\text{CF}_3$ , triplet at 47.97 ppm and  $\text{SF}_2$ , quartet at -52.01 ppm relative to internal  $\text{CCl}_3\text{F}$ , relative peak areas 2.92:2.0, respectively,  $J_{\text{F}-\text{F}} = 10.1$  cps).

**Properties of  $\text{NF}_2\text{CCl}_3$ .** Trichlorodifluoraminomethane exists as a colorless liquid at room temperature and is stable in glass toward mercury up to 55° and is not hydrolyzed by the moisture in the air. Heating  $\text{NF}_2\text{CCl}_3$  at 110° with mercury for 3 hr resulted in formation of  $\text{FN}=\text{CCl}_2$  as the only volatile product. The melting point of  $\text{NF}_2\text{CCl}_3$  was found to be -21° and a boiling point of 56°<sup>4b</sup> was indicated by the Clausius-Clapeyron equation,  $\log P_{\text{mm}} = 8.17 - 1740/T^\circ\text{K}$ . Vapor pressure data are as follows ( $T$ , °K;  $P$ , mm): 242.5, 10.2; 265.6, 40.5; 273.0, 62.2; 285.3, 115.6; 287.8, 130.0; 297.1, 218.7; 304.5, 300.8; 310.0, 373.8; 311.8, 400.8; 317.0, 485.9; 320.8, 560.2; 324.8, 644.7. The molar heat of vaporization is 7.50 kcal and the Trouton constant is 22.8. The experimental molecular weight was found to be 170.5 (calcd, 170.4).  $\text{NF}_2\text{CCl}_3$  gives a single broad peak in the  $^{19}\text{F}$  nmr at  $\phi = -50.8$ . The infrared spectrum (10 mm pressure in a 5-cm cell with KBr windows) is ( $\text{cm}^{-1}$ ): 1024 (m), 912 (s), 884 (vs), 853 (s), 638 (m). The principal peaks in the mass spectrum corresponded to the ions  $\text{Cl}^+$ ,  $\text{CCl}^+$ ,  $\text{FNC}^+$ ,  $\text{NF}_2^+$ ,  $\text{FCCl}^+$ ,  $\text{F}_2\text{NC}^+$ ,  $\text{FNCCl}^+$ ,  $\text{CCl}_2^+$ ,  $\text{F}_2\text{CCl}^+$ ,  $\text{Cl}_2\text{CN}^+$ ,  $\text{F}_2\text{NCCl}^+$ ,  $\text{CFCl}_2^+$ ,  $\text{FNCCl}_2^+$ ,  $\text{CCl}_3^+$  (100%),  $\text{F}_2\text{NCCl}_2^+$ ,  $\text{FNCCl}_3^+$ . All chlorine-containing fragments gave the correct isotopic peaks and relative intensities.

**Properties of  $\text{NF}_2\text{CFCl}_2$ .** Dichlorodifluorodifluoraminomethane is a colorless gas at room temperature and melts at -96°.  $\text{NF}_2\text{CFCl}_2$  is not hydrolyzed by the moisture in air but reacts slowly with mercury. The boiling point was found to be 14°<sup>4c</sup> from a Clausius-Clapeyron plot which is described by the equation  $\log P_{\text{mm}} = 7.80 - 1411/T^\circ\text{K}$ . Vapor pressure data are as follows ( $T$ , °K;  $P$ , mm): 209.5, 12.1; 220.8, 25.7; 230.3, 47.6; 237.3, 72.6; 243.0, 99.7; 246.5, 122.6; 252.8, 165.2; 262.0, 261.8; 268.3, 347.1; 273.0, 423.1; 274.3, 448.9; 277.0, 498.3. The molar heat of vaporization is 6.46 kcal and the Trouton constant is 22.5. The experimental molecular weight was found to be 153.4 (calcd, 153.9). Two resonances were observed in the  $^{19}\text{F}$  nmr, a triplet (relative areas of 1:1.95:1) at  $\phi = 55.55$  assigned to the CF fluorine and a broad overlapping doublet centered at  $\phi = -40.45$  assigned to the  $\text{NF}_2$  group. The relative areas of the  $\text{NF}_2$  and CF resonances were found to be 1.93:1 and  $J_{\text{F}-\text{F}} = 15.8$  cps. The infrared spectrum<sup>4d</sup> (10 mm pressure in a 5-cm cell with KBr windows) is ( $\text{cm}^{-1}$ ): 1147 (s), 1068 (m), 952 (s), 907 (s), 780 (w), 649 (m). The following ions are identified in the mass spectrum:  $\text{CF}^+$ ,  $\text{NF}^+$ ,  $\text{Cl}^+$ ,  $\text{FCN}^+$ ,  $\text{CCl}^+$ ,  $\text{ClCN}^+$ ,  $\text{FNCF}^+$ ,  $\text{FCCl}^+$ ,  $\text{CF}_2^+$ ,  $\text{FNCCl}^+$ ,  $\text{CCl}_2^+$ ,  $\text{ClCF}_2^+$ ,  $\text{F}_2\text{NCCl}^+$ ,  $\text{CFCl}_2^+$  (100%),  $\text{FNCCl}_2^+$ ,  $\text{F}_2\text{NCFCl}^+$ . All chlorine-

containing fragments gave the correct isotopic peaks and relative intensities.

**$\text{NF}_2\text{CFCl}_2 + \text{Hg}$ .**  $\text{NF}_2\text{CFCl}_2$  (0.20 g, 1.30 mmol) and excess mercury were stirred at 100°, in a 125-cc glass vessel fitted with a Teflon stopcock (Kontes Glass Co.), for 6 hr. The volatile products consisted of  $\text{FN}=\text{CF}_2$  (9%), *syn*- $\text{FN}=\text{CFCl}$  (39%) and *anti*- $\text{FN}=\text{CFCl}$  (52%), plus minor amounts of  $\text{SiF}_4$ ,  $\text{FN}=\text{CCl}_2$ , and unreacted  $\text{NF}_2\text{CFCl}_2$  (0.14 mmol). The  $\text{FN}=\text{CFCl}$  isomers were identified by their infrared and  $^{19}\text{F}$  nmr spectra.<sup>7</sup>  $\text{FN}=\text{CF}_2$  and  $\text{FN}=\text{CCl}_2$  were both identified by their infrared spectra.

**$\text{N}_2\text{F}_4 + (\text{CF}_3)_2\text{CO}$ .**  $\text{N}_2\text{F}_4$  (0.457 g, 4.4 mmol) and  $(\text{CF}_3)_2\text{CO}$  (0.73 g, 4.4 mmol) were photolyzed through a Vycor filter until all the tetrafluorohydrazine had reacted. The reaction mixture was passed through traps at -130 and -195°. The -195° trap contained  $\text{NF}_2\text{CF}_3$  (~57.5% yield) and minor amounts of  $\text{N}_2\text{F}_4$ . The product was identified by its infrared<sup>8</sup> and  $^{19}\text{F}$  nmr<sup>9</sup> spectra.

## Results and Discussion

As is recorded in Table I, the yield of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  formed by the photolysis of  $\text{N}_2\text{F}_4$  and  $\text{CSCl}_2$  varies markedly depending upon experimental conditions.  $\text{CSCl}_2$  decomposes to compounds such as  $\text{Cl}_2$ , S,  $\text{CCl}_4$ , and  $\text{CS}_2$ , and dimerizes according to (1) in the presence of ultraviolet light. Thus, when the molar ratio of  $\text{CSCl}_2$  to  $\text{N}_2\text{F}_4$  is increased by one-half, the yield of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  is tripled when a Corex filter is used.

Since  $\text{NF}_2\text{Cl}_2\text{CSCl}$  involves an additional atom of chlorine per molecule of product formed, a second source of chlorine radicals should improve the efficiency of the reaction. The addition of elemental chlorine to the reaction mixture precludes the formation of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  since chlorination of  $\text{CSCl}_2$  to form trichloromethanesulfonyl chloride ( $\text{Cl}_3\text{CSCl}$ ) occurs rapidly at room temperature.<sup>3</sup> Then  $\text{Cl}_3\text{CSCl}$  apparently reacts with  $\text{N}_2\text{F}_4$  to form  $\text{NF}_2\text{CCl}_3$ . The best yields of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  are obtained when sulfinyl chloride is added to the reaction mixture followed by photolysis using a Vycor filter. Previously, we have concluded that  $\text{SOCl}_2$  is decomposed slowly to  $\cdot\text{Cl}$  when photolyzed through Vycor (essentially unaffected if a Corex filter is used).<sup>10</sup> Apparently, under these

conditions  $\text{SOCl}_2$  leads to  $\cdot\text{Cl}$  which, accompanied by the generated  $\cdot\text{NF}_2$ , results in formation of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  at a more rapid rate than  $\text{Cl}_3\text{CSCl}$  which is always found in the product mixture. The effect of the added

$\text{Cl}$  from  $\text{SOCl}_2$  is very pronounced when the yield of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  is compared with that obtained through Vycor earlier. Formation of  $\text{NF}_2\text{Cl}_2\text{CSCl}$  *via* (2) seems a likely route although (3) should be considered. Seel<sup>11</sup> suggested that stepwise fluorination of  $\text{Cl}_3\text{CSCl}$  with  $\text{KF}$  occurs *via* a  $\text{Cl}_3\text{CSF}$  intermediate, rapidly followed by molecular rearrangement to  $\text{Cl}_2\text{FCSCl}$  until complete fluorination is accomplished. Therefore, (3) seems possible but  $\text{Cl}_3\text{CSNF}_2$  is never detected. Varying conditions seem to have little effect on the yield of  $\text{NF}_2\text{CCl}_2\text{F}$ .

Dichlorodifluoraminomethanesulfonyl chloride is a moderately reactive compound with physical properties which resemble  $\text{Cl}_3\text{CSCl}$ . Identification was made by mass spectrum (peaks assigned to  $\text{CS}^+$ ,  $\text{SCl}^+$ ,  $\text{F}_2\text{NCCl}_2^+$ , and  $\text{F}_2\text{NCl}_2\text{CSCl}^+$ ), infrared spectrum ( $\text{S}-\text{Cl}$  stretch at  $541\text{ cm}^{-1}$ ;  $12\text{ N}-\text{F}$  stretches at  $1013$  and  $895\text{ cm}^{-1}$ ), elemental analysis, and  $^{19}\text{F}$  nmr. The single broad  $\text{NF}_2$  resonance at  $\phi -49.9$  compares favorably with  $\text{NF}_2\text{CCl}_3$  at  $\phi -50.8$ . If the other isomer,  $\text{Cl}_3\text{CSNF}_2$ , were formed, the  $\text{NF}_2$  resonance would be shifted much farther downfield as in  $\text{F}_3\text{CSNF}_2$  at  $\phi -103.1$ <sup>13</sup> or even to lower field, as suggested by the data in Table II.

**Table II.**  $^{19}\text{F}$  Nmr of  $\text{NF}_2\text{CF}_x\text{Cl}_{3-x}$  and  $\text{NF}_2\text{CF}_2\text{CF}_2\text{Cl}_{3-x}$  ( $x = 0, 1, 2, 3$ )

Compound	Chemical shifts, $\phi$			Coupling constants, Hz		
	$\text{NF}_2$	$\alpha\text{-F}$	$\beta\text{-F}$			
$\text{NF}_2\text{CF}_3$ <sup>9</sup>	-18.5	84.1		0		
$\text{NF}_2\text{CF}_2\text{Cl}$ <sup>9</sup>	-27.8	62.0		0		
$\text{NF}_2\text{CFCl}_2$	-40.5	55.6		15.8		
$\text{NF}_2\text{CCl}_3$	-50.8					
a b c				$J_{a-b}$	$J_{a-c}$	$J_{b-c}$
$\text{NF}_2\text{CF}_2\text{CF}_3$ <sup>9</sup>	-16.3	119.9	81.8	$\approx 0$	10	$\approx 1$
$\text{NF}_2\text{CF}_2\text{CF}_2\text{Cl}$ <sup>9</sup>	-17.9	116.9	69.7	$\approx 0$	10.0	2.3
$\text{NF}_2\text{CF}_2\text{CFCl}_2$ <sup>9</sup>	-20.7	113.8	72.8	$\approx 0$	14.0	7.2
$\text{NF}_2\text{CF}_2\text{CCl}_3$ <sup>9</sup>	-27.0	108.0				

When an excess of anhydrous potassium fluoride is allowed to react with  $\text{NF}_2\text{Cl}_2\text{CSCl}$  at  $25^\circ$ , the unexpected compound  $\text{CF}_3\text{N}=\text{SF}_2$  is found to be the major product ( $>70\%$  yield). This is an unusual rearrangement in that, in addition to fluorination, the nitrogen atom is shifted between the carbon and sulfur. This

product is not easily rationalized. However, when  $\text{N}_2\text{F}_4$  and  $\text{CF}_3\text{SSCF}_3$  are heated at  $225^\circ$  for 16 hr,  $\text{CF}_3\text{N}=\text{SF}_2$  is formed.<sup>13</sup>

With the synthesis of  $\text{NF}_2\text{CCl}_3$  and  $\text{NF}_2\text{CFCl}_2$ , the series  $\text{NF}_2\text{CF}_x\text{Cl}_{3-x}$  ( $x = 0, 1, 2, 3$ ) is now complete. As is shown in Table II, when chlorine is successively substituted for fluorine, both the  $\text{NF}_2$  and  $\text{CF}$  resonances are shifted farther downfield. A similar trend is noted in other families, *e.g.*,  $\text{NF}_2\text{CF}_2\text{CF}_2\text{Cl}_{3-x}$  ( $x = 0, 1, 2, 3$ ), and may be attributed to delocalization of electron density into available d orbitals on chlorine, which deshields the fluorine atoms. The data also indicate that additional chlorine atoms increase the magnitude of spin-spin coupling constants. The  $\text{NF}-\text{CF}$  coupling for  $\text{NF}_2\text{CFCl}_2$  seems reasonable in light of the increase in  $J$  values from  $\text{NF}_2\text{CF}_2\text{CF}_2\text{Cl}$  to  $\text{NF}_2\text{CF}_2\text{CFCl}_2$ . The surprisingly large coupling of  $15.8\text{ Hz}$  can be explained in terms of a steric effect assuming the major contribution to spin-spin splitting results from direct-through-space interaction.<sup>14</sup>

The volatilities of the compounds  $\text{NF}_2\text{CCl}_3$  and  $\text{CCl}_4$ , and  $\text{NF}_2\text{CCl}_2\text{F}$  and  $\text{CFCl}_3$ , are similar, and, as the data in Table III show, this holds true for other low

**Table III.** Comparison of Volatility of  $\text{X}-\text{Cl}$  and  $\text{X}-\text{NF}_2$  Compounds

Compound	Volatility	
	1 mm	Bp
$\text{Cl}_3\text{C}-\text{Cl}$	$-50^\circ$	$77^\circ$
$\text{Cl}_3\text{C}-\text{NF}_2$	$-60^\circ$	$56^\circ$
$\text{Cl}_2\text{FC}-\text{Cl}$	$-84^\circ$	$24^\circ$
$\text{Cl}_2\text{FC}-\text{NF}_2$	$-92^\circ$	$19^\circ$
$\text{O}$ $\text{ClC}-\text{Cl}$	$-93^\circ$	$8^\circ$
$\text{O}$ $\text{ClC}-\text{NF}_2$	$-102^\circ$	$-5^\circ$
$\text{NF}_2-\text{Cl}$	$-161^\circ$	$-104^\circ$
$\text{NF}_2-\text{NF}_2$	$-179^\circ$	$-117^\circ$

molecular weight compounds when an  $\text{NF}_2$  group is substituted for chlorine. Also, as the molecular weight of the  $\text{X}$  group increases, the volatilities of the  $\text{NF}_2$  and  $\text{Cl}$  compounds approach each other. For example,  $\text{NF}_2\text{Cl}_2\text{CSCl}$  and  $\text{Cl}_3\text{CSCl}$  both have a vapor pressure of  $8\text{ mm}$  at room temperature. Therefore,  $\text{NF}_2$  compounds may be expected to be as volatile or slightly more volatile than their chlorine analogs.

$\text{NF}_2\text{CFCl}_2$  is a useful starting material for the preparation of its imine derivatives by heating with mercury. The reaction is about  $50\%$  complete after 1 week at  $25^\circ$ . The products are a  $50-50$  mixture of *syn*- and *anti*- $\text{FN}=\text{CClF}$  and traces of  $\text{FN}=\text{CF}_2$  and  $\text{FN}=\text{CCl}_2$ . After 6 hr at  $100^\circ$ , reaction is nearly complete, with the *anti* form present in slightly larger amounts. This suggests that the *anti* isomer has greater thermodynamic stability, which is surprising, since *cis*- $\text{N}_2\text{F}_2$  seems to be the thermodynamically favored form. If the  $\text{NF}_2$ -
