Received February 22, 1999

The complex *trans*-[Ru(NH₃)₄NO(H₂O)]Cl₃·H₂O has been isolated as a decomposition product of the dimeric cation [$\{Ru(NH_3)_4NO\}_2(\mu-S_2)\}^{6+}$. The elemental analysis and electronic, infrared, X-ray, and ESR spectroscopies fit well with the formulation *trans*-[Ru(NH₃)₄NO(H₂O)]Cl₃·H₂O. The ν_{NO} (1912 cm⁻¹) observed and the $\angle(Ru-N-O) = 178.1^\circ(5)$ are consistent with the nitrosonium character of the NO ligand. Cyclic voltammetry showed only one redox process in the range -0.5 to +1.2 V, which was attributed to the reaction *trans*-[(H₂O)(NH₃)₄Ru^{II}(NO⁺)]³⁺ + e⁻ $\leftrightarrow$ *trans*-[(H₂O)(NH₃)₄Ru^{II}(NO⁰)]²⁺. The pK_a values 3.1 $\pm$ 0.1 and 7.7 $\pm$ 0.1 ($\mu = 0.10$ M, NaCl) have been measured for the reaction *trans*-[Ru(NH₃)₄L(H₂O)]ⁿ⁺ + H₂O $\leftrightarrow$ *trans*-[Ru(NH₃)₄L(OH)]⁽ⁿ⁻¹⁾⁺ + H₃O⁺, where L = NO⁺ and CO, respectively. The substitution of the coordinated water molecule in *trans*-[Ru(NH₃)₄(H₂O)NO]³⁺ by chloride ions proceeds about 30-fold times slower than in [Ru(NH₃)₅(H₂O)]³⁺ ($k_{Cl^-} = 8.7 \times 10^{-5}$ M⁻¹ s⁻¹ and 3.7×10^{-6} M⁻¹ s⁻¹, respectively; 40 °C, $\mu = 2.0$ NaCl, [H⁺] = 1.0×10^{-2} mol L⁻¹). Quantum mechanical DFT calculations show that the mixing between the lone pair of the oxygen, π in character, and the d_{xz} orbital of the metal is linearly related to the pK_a of the water ligand and to the water lability. The calculations have also shown that the π -d mixing is strongly dependent on the trans ligand L. The electronic spectra of the *trans*-[Ru(NH₃)₄(H₂O)L]ⁿ⁺ (L = CO and NO⁺) species are discussed on the basis of DFT and ZINDO/S calculations.

Introduction

It is well-known that the presence of the NO ligand strongly affects the metal center and the coordination sphere ligand's properties. Then, there is a growing concern over our understanding of how the NO and the ligand in the position *trans* to it influence one another in their chemical behavior. This knowledge would help us to understand how to control the properties of coordination compounds and therefore tailor complex ions to a desired target.

For such a purpose, the *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺ complex is of particular interest. This complex¹ has not been isolated and properly characterized as a solid before, despite the fact that its conjugate base, *trans*-[Ru(OH)(NH₃)₄(NO)]²⁺, has been adequately described in the literature.^{2,3}

This paper describes the synthesis, characterization, and properties of the *trans*-[Ru(NH₃)₄(H₂O)(NO)]Cl₃·H₂O compound. A comparison is made with the isoelectronic complex

trans-[Ru(NH₃)₄(H₂O)(CO)]²⁺. The analysis of the L–Ru–OH₂ bonds and their influence on the water molecule acidity and chemical behavior in the *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺, [Ru(NH₃)₄(H₂O)(CO)]²⁺, and related complexes was also done on the basis of quantum chemical DFT (density functional theory) calculations. Electronic spectra for these complexes were also analyzed on the basis of ZINDO/S calculations performed on optimized DFT structures.

Experimental Section

All preparations and measurements were carried out under an inert atmosphere (argon or nitrogen), using standard techniques.⁴ During the experiments the temperature was controlled within ± 0.2 °C using a Superhom thermostat.

Reagents and Materials. All chemicals were reagent grade (Aldrich or Merck) and were used without further purification. The solvents were purified as described in the literature;⁵ 18 M Ω Milli-Q or doubly

distilled water was used throughout the experiments. Ruthenium trichloride ($\text{RuCl}_3 \cdot 3\text{H}_2\text{O}$) was the starting material for the syntheses of the ruthenium complexes. The ion exchange resin employed was Bio Rad AG-50W X8 (200–400 mesh), in the sodium ion form. Sodium trifluoroacetate (Aldrich) was used as the background electrolyte for the ionic strength control.

Syntheses. The complexes $[\text{RuCl}(\text{NH}_3)_5]\text{Cl}_2$,⁶ *trans*- $[\text{RuCl}(\text{NH}_3)_4(\text{SO}_2)]\text{Cl}$,^{7,8} *trans*- $[\text{RuCl}_2(\text{NH}_3)_4]\text{Cl}$,⁹ *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{CO})]\text{Br}_2$,¹⁰ $[\text{Ru}(\text{NH}_3)_5\text{NO}]\text{Cl}_3$,¹¹ *trans*- $[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]\text{Cl}_2$,¹¹ *trans*- $[\text{Ru}(\text{SO}_3)(\text{NH}_3)_4(\text{NO})]\text{Cl}$,¹² and *trans*- $[\{\text{Ru}(\text{NH}_3)_4\text{NO}\}_2(\mu\text{-S}_2)]\text{Cl}_6 \cdot \text{H}_2\text{O}$ ¹³ were synthesized and characterized following published procedures.

***trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3$.** This compound was isolated during the preparation of $[(\text{NO})(\text{NH}_3)_4\text{RuSSRu}(\text{NH}_3)_4(\text{NO})]\text{Cl}_6 \cdot \text{H}_2\text{O}$.¹³ The latter compound was obtained by reduction of *trans*- $[\text{Ru}(\text{SO}_3)(\text{NH}_3)_4(\text{NO})]\text{Cl}$ (0.3 g) (~1 mmol) with zinc amalgam, in acidic medium (10 mL of 0.05 mol L^{-1} HCl) and under an argon atmosphere. After 10 min, the mixture was filtered in a glovebag and charged onto a cation exchange column (Bio Rad AG-50W X8, sodium ion form). The resin was successively eluted with 0.2, 0.8, 1.5, 2.5, 4.0, and 6.0 mol L^{-1} HCl. From the 1.5 to 6.0 mol L^{-1} HCl eluate a yellow solution was then collected and concentrated by rotary evaporation to $1/10$ of the original volume. The resulting solution was left to cool in a refrigerator for 24 h. A solid precipitated, which was separated by filtration and washed with ethyl alcohol. Yield = 40%. Anal. Calcd for *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$: H, 4.7; N, 20.5; Ru, 29.6; Cl, 31.1. Found: H, 4.4; N, 19.8; Ru, 28.8; Cl, 30.9. Relevant infrared absorption bands,¹⁴ cm^{-1} : 3240 br s [ν_{NH} , ν_{OH}], 1912 s [ν_{NO}], 1637 m [δ_{OH} , δ_{dNH}], 1325 m [δ_{NH}], 959 w [$\nu_{\text{Ru-OH}_2}$], 845 m [$\rho(\text{NH}_3)$, $\delta(\text{NH})_{\text{out of plane}}$], 614 w [$\nu_{\text{M-NO}}$], 570 w [$\delta_{\text{Ru-NO}}$], and 481 w [$\nu_{\text{M-NH}_3}$], where br = broad, s = strong, m = medium, and w = weak.

The *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ can also be obtained from the treatment of *trans*- $[\text{Ru}(\text{HO})(\text{NH}_3)_4\text{NO}]^{2+}$ with concentrated $\text{CF}_3\text{SO}_3\text{H}$ (8 mol L^{-1}).

Instrumentation. The elemental analyses were carried out at the Instituto de Química da Universidade de São Paulo. The ruthenium analysis was performed according to the method of Rowston and Ottaway,¹⁵ modified by Clarke,¹⁶ using a Polarized Zeeman atomic absorption spectrophotometer, Hitachi (model Z-8100).

UV-visible measurements were performed in a 1.0 cm quartz cell on a Hewlett-Packard diode array model 8452A spectrophotometer. IR spectra were recorded on a Bomem FTIR, model MB-102, spectrophotometer in the 300–4000 cm^{-1} range, in KBr pellets and by diffuse reflectance. ESR experiments were carried out on a Bruker ESR 300E spectrometer, at the liquid N_2 temperature.

A polarographic analyzer/stripping voltammeter model 264A from Princeton Applied Research attached to a microcomputer employing Microquímica eletrochemical software was used for the electrochemical measurements. The electrochemical cell used was a conventional three-electrode type with an aqueous saturated calomel electrode (SCE) as a reference electrode and glassy-carbon and platinum wire as working and auxiliary electrodes, respectively.

Table 1. Crystallographic Data for *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$

The acidity of the coordinated water molecule in *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})\text{L}]^{n+}$ ($\text{L} = \text{NO}^+$, CO) was determined by potentiometric titration¹⁷ with (0.01 M) NaOH solution. For $\text{L} = \text{NO}^+$, a potentiometric titration of *trans*- $[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]^{2+}$ with (0.01 M) HCl solution, $\mu = 0.10$ mol L^{-1} , was also performed. All measurements were run in triplicate using compounds from different preparations.

All of the kinetic anations were followed using a Hewlett-Packard diode array model 8452A recording spectrophotometer. Temperatures of the experiments were fixed to 40.5 ± 0.5 °C and controlled by a thermostated Tecnal TE 184 temperature bath. *trans*- $[\text{Ru}(\text{NH}_3)_4\text{NO}(\text{H}_2\text{O})]^{3+}$ and $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$ solutions were prepared by dissolving the respective solids in degassed 2.0 mol L^{-1} chloride solutions (1.0×10^{-2} mol L^{-1} CF_3COOH , $\mu = 2.0$) and quickly transferred to a quartz 1 cm spectrophotometric cell which was glass-sealed.

Crystals of *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$ for X-ray diffraction were obtained from an aqueous solution of 6.0 mol L^{-1} HCl kept in a refrigerator for 48 h. A crystal of this compound was mounted in the Enraf-Nonius CAD4 diffractometer, at 243 K, and, using 25 reflections automatically centered, the cell parameters were obtained and refined. Table 1 shows the data collection and refinement conditions. The intensity data were reduced to F_o and corrected by absorption factors (μ ($\text{K}\alpha\text{Mo} = 20.7$ cm^{-1}) by the PSISCAN method.¹⁸

The structure was solved by Patterson function and difference Fourier synthesis and refined by full-matrix least squares.¹⁸ The hydrogen water atoms were found in the DF map, and the others are located in their ideal positions and not refined, using $d(\text{N-H}) = 0.960$ Å and thermal vibration equal to 4.0 Å². All non-hydrogen atoms were refined anisotropically, and the atomic scattering factors were those from Cromer and Mann¹⁹ with anomalous dispersion from Cromer and Liberman,²⁰ and for the hydrogen atoms from Stewart et al.²¹

The quantum chemical calculations were carried out at the ab initio level, using the B3LYP DFT method and 3-21G as the basis set, both standard in the quantum chemistry computational package GAUSSIAN-94.²² The simulated electronic spectra were obtained by configuration interaction (CI) at the semiempirical level and at the DFT optimized geometry, using the ZINDO/S method from the HyperChem4.5 package.²³

Results and Discussion

Molecular and Crystal Structure. Table 1 shows some of the X-ray data for $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3$, and Figure 1 displays the ORTEP²⁴ view with the atom labeling scheme. Table 2 shows relevant observed and calculated interatomic distances for this and related complexes.

The X-ray data for $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$ indicate only a minor distortion from an idealized C_{4v} symmetry. This distortion is smaller than those seen for the $\text{trans-}[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]\text{Cl}_2$ and $[\text{Ru}(\text{NH}_3)_5(\text{NO})]\text{Cl}_3$ complexes.^{3b} The Ru-N-O angle in the aqua complex is 178.1(5)°, very close to the reported values for $\text{trans-}[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]\text{Cl}_2$ (173.8(3)°)^{3b} and $[\text{Ru}(\text{NH}_3)_5(\text{NO})]\text{Cl}_3$ (172.8(9)°).^{3b} These data are in agreement with the observed ν_{NO} (1912 cm⁻¹) and the fact that the $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$ is ESR silent, thus, strongly suggesting the nitrosonium character of the NO ligand in this complex. The X-ray bond lengths for Ru-NH₃ are 2.093(5), 2.093(6), 2.099(5), and 2.107(5) Å, respectively, for N(1), N(2), N(3), and N(4).

The Ru-NO bond length in $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$ is quite short, 1.715(5) Å, and is close to the reported values for the similar bond in $\text{trans-}[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]\text{Cl}_2$ (1.735(3) Å)^{3b} and $[\text{Ru}(\text{NH}_3)_5(\text{NO})]\text{Cl}_3$ (1.770(9) Å),^{3b} but much smaller than the Ru-NH₃ distance in several Ru(II) and

Ru(III) ammine complexes, which is in the 2.1 ± 0.1 Å range.^{3b,7,25a-p} This short distance in the nitrosyl complexes is consistent with the strong Ru(II)-NO $d_{\pi} \rightarrow \pi^*\text{NO}$ back-bonding. The shorter Ru-N(azine or diazine) interatomic distances for the Ru(II) compared with the respective Ru(III) complexes in ruthenium ammines with such π -acceptor ligands is explained as a result of this back-bonding in Ru(II), such as illustrated by the $[\text{Ru}^{\text{II}}(\text{NH}_3)_5(\text{pz})](\text{BF}_4)_2/[\text{Ru}^{\text{III}}(\text{NH}_3)_5(\text{pz})](\text{CF}_3\text{SO}_3)_3 \cdot \text{H}_2\text{O}$ (2.006 Å for Ru(II) and 2.076 Å for Ru(III))^{25h} and $[\text{Ru}^{\text{II}}(\text{NH}_3)_5(\text{mpz})]\text{I}_3/[\text{Ru}^{\text{III}}(\text{NH}_3)_5(\text{mpz})](\text{tos})_4 \cdot 5\text{H}_2\text{O}$ (mpz = 1-methylpyrazinium; tos = tosylate (*p*-toluenesulfonate) (1.95 Å for Ru(II) and 2.08 Å for Ru(III)) complexes.^{25k} It is noteworthy that in the 1-methylpyrazinium-Ru(II) complex a Ru(mpz) double bond was suggested to occur.^{25g} Thus, on the basis of interatomic distances, the Ru-NO bonds in the above nitrosyl complexes is shorter than expected for a double bond. The N-O distance in $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3 \cdot \text{H}_2\text{O}$ is 1.142(7) Å, similar to the distance reported for $\text{trans-}[\text{Ru}(\text{OH})(\text{NH}_3)_4(\text{NO})]\text{Cl}_2$ (1.159(5) Å)^{3b} and $[\text{Ru}(\text{NH}_3)_5(\text{NO})]\text{Cl}_3$ (1.172(14) Å).^{3b} These short NO interatomic distances are consistent with a NO⁺ fragment with an unfilled π^* MO and also consistent with the observed NO stretching frequency values (ν_{NO}) of 1912 and 1850^{2b} cm⁻¹ for the aqua and hydroxo compounds, respectively.

As expected, the ruthenium-oxygen distance in the Ru-OH fragment of the hydroxotetraammine species, 1.961(3) Å,^{3b} is shorter than that observed for the ruthenium-oxygen distance Ru-OH₂ in $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]\text{Cl}_3$ (2.035(5) Å).

Electrochemical Properties. Only one monoelectronic redox process was observed in the range -0.5 to +1.2 V vs SCE for $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$, which has been attributed to the electron transfer process at the NO ligand. The observed $E_{1/2}$ value ($(E_{1/2})_{\text{NO}^+/\text{NO}^0} = -0.39 \pm 0.01$ V vs SCE) is in good agreement with the expected one (-0.43 V)^{25a} on the basis of the empirical correlation ν_{NO} versus $E_{1/2}$ observed for the tetraamminenitrosylruthenium analogues.^{26a} As observed for other nitrosyl ruthenium-ammine complexes,^{12,26} the ruthenium(II) center is not electroactive in the potential range mentioned above. The NO⁺ + e⁻ → NO⁰ electron transfer is reversible, followed by a chemical reaction in which the NO⁰ ligand undergoes an aquation reaction to yield $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})_2]^{2+}$. The formation of this latter species was confirmed by the spectrophotometric detection of $\text{trans-}[\text{Ru}(\text{NH}_3)_4(\text{pz})_2]^{2+}$

upon reduction of (1.0 $\times$ 10⁻³ M) $trans$ -[Ru(NH₃)₄(H₂O)-(NO)]³⁺ with Cd(Hg) followed by addition of pyrazine (1 M).

The observed electrochemical behavior for the aqua nitrosyl ion is consistent with that described for other $trans$ -[Ru(NH₃)₄-(NO)L]³⁺ complexes^{12,26} and can be explained by the scheme

Protonation Equilibria. The pK_a 's for the reaction

was calculated from potentiometric titrations, as 3.1 $\pm$ 0.1 (L = NO⁺) and 7.7 $\pm$ 0.1 (L = CO), respectively.

The acidity of a ligand in a complex is influenced by the nature of the trans ligand. This is illustrated by the pK_a changes of the coordinated pyrazine in the *trans*-tetraammine(pyrazinium)ruthenium complexes with different *trans*-L ligands (NH₃, py, pz, pzH⁺)²⁷ (see Table 3). In these complexes, the pK_a order decreases as increases the acidity of the trans ligand L, NH₃ > py > pz > pzH⁺. This order is consistent with both the increasing π -acceptor and decreasing σ -donor strengths of the ligand, which did not allow a proper evaluation of the individual contribution of each factor.^{27b,c} Examination of Table 3 shows that the pK_a of $trans$ -[Ru(NH₃)₄(H₂O)(CO)]²⁺ (7.7) is smaller than those of the isonicotinamide derivative, $trans$ -[Ru(NH₃)₄-(H₂O)(isn)]²⁺ (11.7),²⁸ and [Ru(NH₃)₅(H₂O)]²⁺ (13.1).²⁸ This decrease is consistent with the higher π -acceptor and smaller σ -donor strength of CO compared with those of ammonia and

isonicotinamide. Changing the trans ammonia ligand to NO⁺, in [Ru(NH₃)₅(H₂O)]²⁺, results in a dramatic decrease in the H₂O ligand pK_a of 10 orders of magnitude (13.1 for NH₃ and 3.1 for NO⁺). The nitrosyl is considered to have a lower σ -donor and a higher π -acceptor strength than the isoelectronic CO,²⁹ resulting in, as an overall effect, a higher electron acceptor strength for nitrosyl.²⁹ This effect is such that the pK_a for the water ligand in the Ru(II) complex $trans$ -[Ru(NH₃)₄(H₂O)-(NO)]³⁺ (3.1) is even lower than that in the Ru(III) complex [Ru(NH₃)₅(H₂O)]³⁺ (4.1),³⁰ which in turn is 9 orders of magnitude lower than that in its Ru(II) homologue [Ru(NH₃)₅-(H₂O)]²⁺ (pK_a of the 13.1).²⁸ Thus, replacing NH₃ for NO⁺ would turn the Ru(II) fragment even harder than Ru(III) in [Ru-(NH₃)₅(H₂O)]³⁺. As a matter of fact, this high water acidity had been anticipated earlier for these NO and CO complexes by Taube.³¹

In addition, the strong influence of the NO on the acidity of the trans ligand is also observed in the $trans$ -[Ru(NH₃)₄(pz)-(NO)]³⁺ complex. While the pK_a value for [Ru(NH₃)₅(pzH)]³⁺ is 2.5,^{27a} the $trans$ -[Ru(NH₃)₄(pz)(NO)]³⁺ species, as far as the electronic spectrum is concerned, does not undergo protonation¹³ even in 2.0 mol L⁻¹ HCl. This observation suggests that pz in $trans$ -[Ru(NH₃)₄NO(pz)]³⁺ exhibits an acidity higher than that for $trans$ -[Ru(NH₃)₄(pz)(py)]²⁺, $trans$ -[Ru(NH₃)₄(pz)(pzH)]³⁺, $trans$ -[Ru(NH₃)₄(pzH)(pzH)]⁴⁺, and [Ru(NH₃)₅(pzH)]⁴⁺ (see Table 3).

The presence of the nitrosyl ligand seems also to exercise a large effect upon the coordinated water lability and the affinity of the Ru(II) center to π -acid ligands. Indeed, as far as the voltammetric and electronic spectra are concerned, no formation of $trans$ -[Ru(NH₃)₄(NO)(pz)]³⁺ was observed when the $trans$ -[Ru(NH₃)₄(H₂O)(NO)]³⁺ complex was left in the presence of 1.0 M pz (100 times the stoichiometric amount), after 48 h of standing (40 °C, pH 1.5 KCl/HCl). This observation is quite interesting considering that pz substitutes H₂O in [Ru(NH₃)₅-(H₂O)]²⁺ at the specific second-order rate constant of 5.6 $\times$ 10⁻² M⁻¹ s⁻¹ and the affinity of pz for the $trans$ -[Ru(NH₃)₅-(H₂O)]²⁺ moiety was calculated³¹ as 10¹² M⁻¹.

Another example of the remarkable reduction of the water ligand lability comes from the experiments using Cl⁻ as an entering ligand on [Ru(NH₃)₅(H₂O)]³⁺ and on $trans$ -[Ru(NH₃)₄-(H₂O)(NO)]³⁺. The replacement of the water molecule by Cl⁻ in the pentaamine species ($k_{Cl^-} = 8.7 \times 10^{-5}$ M⁻¹ s⁻¹) takes place 30-fold times faster (2.0 mol⁻¹ L NaCl, 0.01 mol⁻¹ L CF₃COOH and at 40.0 $\pm$ 0.5 °C) than in $trans$ -[Ru(NH₃)₄(H₂O)-(NO)]³⁺ ($k_{Cl^-} = 3.7 \times 10^{-6}$ M⁻¹ s⁻¹), for the same experimental conditions. Similar to what was observed in the comparison of pK_a values, the delabilizing effect of NO upon the trans water ligand and on the affinity of the Ru(II) for π -acid ligands is dramatic and higher than expected on the basis of the one unit increase in the metal center charge.

The above observations are also consistent with the reported relative substitution inertness of chloride in acidic medium in $trans$ -[RuCl(NH₃)₄(NO)]²⁺^{2k} and with our results³² from a related study on the dimer $trans$ -[Ru(NH₃)₄(NO)]₂(μ -Cl)]⁵⁺. Despite the well-known low affinity^{1d} of the [Ru(NH₃)₅]²⁺ center for Cl⁻, the chloride bridge in this complex is quite strong, indicative of the high Ru(II) center σ acidic character in such compounds. Aqueous solutions (pH $\sim$ 3) of $trans$ -[Ru(NH₃)₄-

(NO)₂(μ-Cl)Cl₅ are stable for more than 48 h, but, with the addition of Eu(II), the NO⁺ ligand is reduced to NO⁰ and the dimer readily decomposes, according to

as indicated by UV-vis, cyclic voltammetry, and conductometric chloride ion titration experiments.³²

Molecular Orbital Calculations and Electronic Spectra. Table 4 shows the calculated DFT MO energy levels for the *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺, *trans*-[Ru(NH₃)₄(H₂O)(CO)]²⁺, [Ru(NH₃)₅(H₂O)]²⁺, and [Ru(NH₃)₅(H₂O)]³⁺ complexes. Figure 2 shows schematic MO diagrams for the NO⁺ and CO complexes, under C_{2v} symmetry. The z axis is coincident with the C₂ symmetry axis in these complexes. The CO and the nitrosyl species each have two π* orbitals of appropriate energies and symmetry to combine with two d_π Ru(II) orbitals, d_{xz} and d_{yz}. For the hydroxo complexes with these two trans

**Figure 2.** Relevant molecular orbitals and qualitative energy level scheme for (a) *trans*-[Ru(NH₃)₄CO(H₂O)]Cl₂ and (b) *trans*-[Ru(NH₃)₄-NO(H₂O)]Cl₃.

ligands, the oxygen center has also two π* orbitals, parallel to the x and y axes, available for combination with the d_{xz} and d_{yz} Ru orbitals and with the π* CO and nitrosyl orbitals, forming in this case six MO's involving L-Ru-OH. In its turn, the trans π-donor H₂O has a lone pair of π symmetry (assumed parallel to the x axis), which is able to combine with the d_{xz} metal orbital. The combination of these orbitals leads, for the aqua complexes, to a five molecular orbital set rather than six as for the hydroxo. Also a d_π orbital splitting is observed.

The sets of five MO's in the CO and NO⁺ aqua complexes comprise the ψ₁, ψ₂, ψ₃, ψ₈, and ψ₉ orbitals for CO and the ψ₁, ψ₂, ψ₃, ψ₅, and ψ₆ orbitals for NO⁺. For both complexes, as can be seen in Figure 2, the HOMO orbital, ψ₄ (Ru d_{xy}), is nonbonding in character. All other five remaining orbitals (ψ₁, ψ₂, ψ₃, ψ₈, and ψ₉ orbitals for CO and ψ₁, ψ₂, ψ₃, ψ₅, and ψ₆ orbitals for NO⁺) have a contribution from either p_y-π* or p_x-π* CO or NO orbitals, while only ψ₁, ψ₃, and ψ₈ (for the CO complex) and ψ₁, ψ₃, and ψ₅ (for the NO complex) have a contribution from the water oxygen p_xπ orbital, since the MO involving the yz components would be nonbonding with respect to Ru-O. So, this set of five orbitals involves a combination of the Ru d_{yz} orbital with the CO or NO p_y-π* orbital, resulting in one bonding and one antibonding molecular orbital (ψ₂ and ψ₉ for CO, and ψ₂ and ψ₆ for NO⁺), the first one (ψ₂) giving rise to the back-bonding stabilization energy (bbse). The d_{xz} orbital would give rise to a similar orthogonal set of orbitals with the same energies if there were not a water trans to NO or CO. The presence of the water oxygen π orbital results in three extended three-centered molecular orbitals (ψ₁, ψ₃, and ψ₈ for CO; ψ₁, ψ₃, and ψ₅ for NO⁺), derived from the combination of the following orbitals: Ru d_{xz}, CO or NO p_x-π*, and the water O orbital of π symmetry oriented through the x axis. The completely bonding, lowest energy MO (ψ₁), for both complexes, would be close in energy to the water O orbital, from which it has the major contribution (52%). The next one, ψ₂, for both complexes has a contribution from the d_{yz} orbital and the CO or NO p_y-π* orbitals. The bonding ψ₃ orbitals have a greater contribution from the d_{xz} orbital (65%). In the absence

Figure 3. Correlation between pK_a and (a) percentage of the π -oxygen orbital to the ψ_3 orbital and (b) calculated Mulliken charge on the metal centers.

of the O orbital, the d_{xz} orbital would have the same energy as the above-described bonding orbital with the d_{yz} orbital, ψ_2 ; the ψ_3 orbitals are higher in energy given the O orbital contribution (5.7% and 11.7% for CO and NO^+ , respectively). In fact, considering that H_2O is not a π -acceptor (and, thus, does not contribute to a higher back-bonding), but rather a π -donor,³³ although poor, its presence would lead to an increase in the energy. Actually, the strong trans L π -acceptor ability, which “hardens” the Ru(II) core, would favor the H_2O π -donation. The third orbital (ψ_8 for CO and ψ_5 for NO^+) is antibonding with respect to Ru–L and Ru–O and has a higher contribution from the L p_z – π^* orbital. For $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{2+}$ and $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$, the presence of the saturated trans NH_3 ligands results in a set of two MO’s derived from the combination of a d_{xz} orbital with the water O π -donor orbital, with a much lower d_{xz} contribution to the bonding orbital in the Ru(II) complex, and a higher one in Ru(III), as a result of the charge and increased π -acceptor ability of the metal center. Removal of one electron from $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{2+}$ results in $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$, with the d_{xy} orbital as the monoelectronic HOMO orbital. This removal breaks up the degeneracy of the α (spin up) and β (spin down) forms, as shown in Table 4. The empty β -form d_{xz} orbital is moved to high energy, and the mixing between the O p_x orbital and the metal d_{xz} orbital occurs only for the α -form d_{xz} orbital.

The contributions of the water oxygen orbital of π symmetry to the ψ_3 orbital are 1.5%, 5.7%, and 11.7%, for *trans*-L = NH_3 , CO, and NO^+ , respectively, and 11.8% for $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$. Noteworthy also is a close correlation between these values and the pK_a values of these complexes (see Table 3). In fact, this means that, as the water O orbital contribution increases, the charge density on the water O decreases, resulting in a lower pK_a . This can be easily seen by plotting the pK_a values vs the calculated charge on the metal center (Figure 3). This can be regarded as a rather reasonable correlation if we consider the experimental uncertainties and peculiarities of the theoretical model.³⁴ It should be noted that, although displaying close values, the pK_a ’s and the calculated Mulliken charge on the

metal center of $[\text{Ru}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$ and *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ also follow that trend. In addition to the above considerations, in the aqua complexes the lowest energy orbital, ψ_1 , involving the metal d_{xz} and the oxygen orbital of π symmetry strengthens the Ru–O bond and, consequently, weakens the O–H bonds, thus decreasing the pK_a .

Important differences between the molecular orbital levels of the *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ and *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{CO})]^{2+}$ complexes are found for the MO’s from ψ_5 to ψ_9 . The CO complex ψ_8 and ψ_9 orbitals correspond to the NO complex ψ_5 and ψ_6 orbitals, respectively. The energies of the NO ψ_7 and ψ_8 orbitals are closer in energy to the Ru(II) d_{xy} nonbonding orbital, ψ_6 , whereas the CO ψ_8 and ψ_9 orbitals are higher. The energies of ψ_8 and ψ_9 for the CO complex are, respectively, $\sim -63\,000$ and $\sim -62\,100\text{ cm}^{-1}$, respectively differing by $\sim 48\,400$ and $\sim 49\,300\text{ cm}^{-1}$ from the energy of the LUMO ψ_7 orbital. The energies of ψ_7 and ψ_8 for the NO complex are, respectively, $\sim -131\,500$ and $\sim -131\,000\text{ cm}^{-1}$, and their respective gaps $\psi_7 - \psi_6$ and $\psi_7 - \psi_8$ are respectively $\sim 34\,800$ and $\sim 35\,400\text{ cm}^{-1}$. The NO complex ψ_7 and ψ_8 orbitals are lower in energy than the d_{π} orbitals of t_{2g} parentage, namely, ψ_9 and ψ_{10} . For the CO complex it should be pointed out that ψ_{10} and ψ_{11} are the highest in energy, and, noteworthily, the LUMO orbital, ψ_7 , is essentially 5s (more than 90%) in character, while the LUMO for the nitrosyl complex, ψ_7 , would have a contribution from the NO ligand p_x – π^* orbital ($\sim 73\%$). These features should be reflected in some of the complexes’ properties.

The nature of the combinations results in some interesting features. The NO complex ψ_5 and ψ_6 orbitals have a rather large d_{π} contribution ($\sim 27\%$), while the corresponding ψ_8 and ψ_9 orbitals for the CO complex have 13.9% of d_{π} contribution. Accordingly, transitions to these levels would have more metal to ligand charge transfer (MLCT) character in the carbonyl than in the nitrosyl complex.

Electronic Spectra. The electronic spectrum of the *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ ion in solution is shown in Figure 4. This spectrum shows some similarities to the spectra of other *trans*-tetraamminenitrosyl complexes (*trans*- $[\text{Ru}(\text{NH}_3)_4(\text{NO})\text{L}]^{n+}$ (L = NH_3 , OAc^- (acetate), Cl^- , OH^- , NCO^- , N_3^- or Br^- ;^{2k} L = isn, pz, SO_3^{2-} , or NO_2^- ;¹² L = imN (imidazole), L-hist (L-histidine), py (pyridine), or nic (nicotinamide);^{26a} and L = $\text{P}(\text{OEt})_3$ (triethyl phosphite)). These complexes usually display at least three or four absorption bands in the UV–vis range, depending on the nature of the ligand trans to NO. The spectral assignments for these complexes (L = isn, pz, SO_3^{2-} , or NO_2^- ;¹² L = $\text{P}(\text{OEt})_3$;^{26b} and L = imN, L-hist, py, or nic^{26a}) were made using Schreiner’s assignments^{2k} for L = NH_3 , OAc^- , Cl^- , OH^- , NCO^- , N_3^- , or Br^- . These complexes display a very weak and broad absorption band in the 400–500 nm range. A very weak and broad absorption band ($\lambda_{\text{max}} = 426$, $\epsilon = 45\text{ mol}^{-1}\text{ L cm}^{-1}$) is also observed in the electronic spectrum of the *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ ion. These low-energy bands for the former complexes were assigned^{2k} as a mixture of two transitions: one ligand-field (LF) spin-forbidden ($^1A_1 \rightarrow ^3T_1$) and one charge transfer process [$t_{2g} \rightarrow \pi^*(\text{NO})$], which would be a metal to ligand charge transfer (MLCT). The assignment of the absorption band at 426 nm in the spectrum of *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ as a one charge transfer process [$t_{2g} \rightarrow \pi^*(\text{NO})$], regardless of spin considerations, does not agree with the MO’s described above for the *trans*- $[\text{Ru}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO})]^{3+}$ complex. According to our calculations, for this aqua complex, both ψ_5

Figure 4. Electronic spectra of *trans*-[Ru(NH₃)₄NO(H₂O)]Cl₃ in 0.1 mol L⁻¹ CF₃COOH: (A) 6.5×10^{-4} mol L⁻¹ and (B) 9.6×10^{-4} mol L⁻¹.

and ψ_6 have a metal orbital contribution. As a matter of fact, in these species, all orbitals that have an NO orbital contribution would have also a metal orbital contribution. Thus, transitions involving exclusively these orbitals, for *trans*-[Ru(NH₃)₄(H₂O)-(NO)]³⁺, although displaying some CT character, could not be described as purely MLCT in character. A spin-forbidden ligand-field (LF) transition contributing to the 426 nm absorption in *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺ cannot be completely ruled out. For similar systems, such as the isoelectronic *trans*-[Ru(NH₃)₄(H₂O)(CO)]²⁺,³⁵ the lowest energy bands are singlet and mostly LF in character, as also occurs^{35,36} for *trans*-[Ru(NH₃)₄(P(OR)₃)-(CO)]²⁺, *trans*-[Ru(NH₃)₄(P(OR)₃)₂]²⁺, and *trans*-[Ru(NH₃)₄(H₂O)(P(OR)₃)]²⁺. These bands occur in the 300–400 nm range, and no triplet bands were observed in these systems. Furthermore, the spectroscopically nonobserved lowest energy triplet LF bands of [Ru(NH₃)₅(py)]²⁺ and [Ru(NH₃)₆]²⁺ were determined to occur at $\approx 1.7 \times 10^4$ cm⁻¹ (588 nm).³⁷ In the ammine-ruthenium(II)–nitrosyl complexes these levels could be expected to lie at higher energy, given the very strong LF character of NO. In addition there would be a larger splitting of the d orbitals. Accordingly, the d_{z²} and d_{x²-y²} orbitals would split, with one higher and the other lower in energy, which would result in the splitting of the bands toward higher and lower energies, respectively. However, a definite statement would be hard to make given the different nature of the molecular orbitals involved in the complexes, with NO, CO, and the other unsaturated ligands, despite their apparent similarity. This can be illustrated by the MO diagrams of the NO and CO complexes where the energetic order of the unoccupied orbitals is different in both complexes (see below).

The absorption bands of *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺ were assigned using semiempirical CI ZINDO/S calculations (Table 5). Seven transitions comprise the band at 426 nm, involving transitions from ψ_2 or ψ_3 to ψ_5 or ψ_6 and from ψ_4 to ψ_5 or ψ_6 . These latter two have some MLCT character, since the non-bonding ψ_4 is purely metal in character. The second absorption band ($\lambda_{\text{max}} = 322$, $\epsilon = 280$ mol⁻¹ L cm⁻¹) of *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺ can be assigned to a spin-allowed d–d transition: d_{xy} → d_{x²-y²} (¹A₁ → ¹A₂) ($\psi_4 \rightarrow \psi_8$). The third band ($\lambda_{\text{max}} = 235$, $\epsilon = 2.5 \times 10^3$ mol⁻¹ L cm⁻¹) can be assigned to a combination of seven transitions from ψ_3 or ψ_5 to ψ_7 or ψ_8

(Table 5). Transitions involving ψ_7 and ψ_8 are essentially LF in character. These assignments are in agreement with those of Gray and Manoharan³⁸ for the nitroprusside ion.

The electronic spectrum of the ion *trans*-[Ru(NH₃)₄(H₂O)-(CO)]²⁺ (Table 6) shows some different features, compared to that of *trans*-[Ru(NH₃)₄(H₂O)(NO)]³⁺. In the carbonyl species spectrum, there is an absorption band at 240 nm ($\epsilon = 420$ mol⁻¹ L cm⁻¹), and there is another at 282 nm ($\epsilon = 440$ mol⁻¹ L cm⁻¹), with one shoulder on the lower energy side. A Gaussian deconvolution of the spectrum shows an absorption component

at 358 nm ($\epsilon = 54 \text{ mol}^{-1} \text{ L cm}^{-1}$), as occurs with the spectrum of *trans*-[Ru(NH₃)₄(P(OR)₃)(CO)]²⁺,³⁵ which displays two bands. The higher energy band in this latter complex was assigned, under C_{4v} symmetry, to a $^1A_1 \rightarrow ^1E$ transition, and the lower energy band to a $^1A_1 \rightarrow ^1A_2$ transition.³⁵ The photochemical behavior of *trans*-[Ru(NH₃)₄(P(OR)₃)(CO)]²⁺³⁴ is consistent with the spectral assignment.³⁵ However, for *trans*-[Ru(NH₃)₄(H₂O)(CO)]²⁺, the assignment of the bands³⁵ following the same model above (282 nm, $^1A_1 \rightarrow ^1E$; 358 nm, $^1A_1 \rightarrow ^1A_2$) leads to some discrepancies regarding the expected and the observed photochemical behavior of the complex.³⁵ Using semiempirical CI ZINDO/S calculations, although approximate for electronic spectra, the band at 282 nm can be assigned to three transitions (from ψ_2 , ψ_3 , or ψ_4 to ψ_6), LF in character. The shoulder at 358 nm can be assigned to a $^1A_1 \rightarrow ^1A_2$ (ψ_4 to ψ_7 or d_{xy} to $d_{x^2-y^2}$) transition. These assignments, using C_{2v} symmetry, are not dramatically different from the former,³⁵ using C_{4v} symmetry, but are not consistent with the photochemical behavior of the complex. The band at 240 nm can be assigned to a combination of six transitions, two of them ($\psi_4 \rightarrow \psi_8$ and $\psi_4 \rightarrow \psi_9$) being MLCT in character. These two assignments imply that the lowest energy band would not have a contribution from the d_{z^2} orbital. However, the photochemical results indicate photolabilization of the CO ligand, therefore suggesting that the d_{z^2} orbital should contribute to some extent to the lowest energy excited state.³⁵

Conclusions

The substitution of the *trans* NH₃ ligand in the Ru coordination sphere by the NO ligand makes the ruthenium(II) center a stronger Lewis acid than the formally Ru(III) center in [Ru(NH₃)₅(H₂O)]³⁺ and at the same time markedly decreases

the lability of the coordinated water and the affinity of the Ru(II) center for π -acid ligands. The experimental data show that the presence of the nitrosyl ligand affects the metal center properties more than expected by increasing its charge by one unit. Thus, the explanations for the acidic character of the water and its kinetic delabilization go beyond only the metal's formal charge. Molecular orbital analyses performed at the quantum chemical DFT level show that the lone pair of the water, π in character, plays an important role in the metal–water bond properties. The involvement of d_{π} orbitals in the metal–water bond results in a depletion of electronic density on the oxygen, increasing the water acidity. The pK_a 's of the coordinated water in a series of complexes are linearly related to the calculated mixing between the water oxygen p_x orbital of π symmetry and the metal d_{xz} orbital.

Acknowledgment. We thank Prof. Jeff Curtis (USF Chem Department, San Francisco) and Prof. C. Peter Ford (UC, Santa Barbara) for helpful discussions and Prof. Bruce McGarvey for reading and commenting on the manuscript. The authors are indebted to the Brazilian agencies CNPq, CAPES, and FAPESP (Grant 92/351503) for financial support. S.C.S is thankful to FAPESP for a postdoctoral fellowship (Grant 95/02789). The loan of RuCl₃ from Johnson & Mathey is also acknowledged.
