

NEW SYNTHESIS OF 4-METHYL-2-METHYLAMINO-5-(N-METHYLTHIOCARBAMOYL)-  
THIAZOLE BY THERMAL ISOMERIZATION

A reaction of 4-methyl-2-methylaminothiazole (I) with methyl isothiocyanate gave 1,3-dimethyl-1-(4-methylthiazol-2-yl)thiourea (IIa), whose structure was established by an X-ray analysis. A thermal isomerization of (IIa) gave 4-methyl-2-methylamino-5-(N-methylthiocarbamoyl)thiazole (IIIa) in a good yield.

The reaction of 4-methyl-2-methylaminothiazole (I) with methyl isothiocyanate in toluene in the presence of pyridine gave the crystals of mp 56-57°C (IIa) having Rf value of 0.75 (2-propanol:ether, 1:1),  $\lambda_{\max}$  (2-propanol) 260 (sh.), 291 nm ( $\epsilon=19500$ ) and yellow crystals of mp 249-250°C (IIIa) having Rf value of 0.53,  $\lambda_{\max}$  (2-propanol) 294 ( $\epsilon=6310$ ), 340 nm ( $\epsilon=11500$ ).

The elemental analysis and mass spectral data (MW 201) gave a molecular formula of C<sub>7</sub>H<sub>11</sub>N<sub>3</sub>S<sub>2</sub> for both (IIa) and (IIIa), isomeric to each other. The thermal isomerization of (IIa) in pyridine gave (IIIa). As the spectral interpretation could not differentiate 1,3-dimethyl-1-(4-methylthiazol-2-yl)thiourea (IIa) and 4-methyl-2-methylimino-3-(N-methylthiocarbamoyl)-4-thiazoline (IVa), the structure of (IIa) was established by an X-ray analysis.

The NMR spectrum (d<sub>6</sub>-DMSO) of (IIIa) showed signals at  $\delta$  2.29 (singlet, 3H, =C-CH<sub>3</sub>), 3.10 (doublet, 3H, J=5.0 Hz, singlet after D<sub>2</sub>O exchange, singlet after irradiation at 9.06, -NH), 2.28 (doublet, 3H, J=5.0 Hz, singlet after D<sub>2</sub>O exchange, singlet after irradiation at 7.86, -NH), 9.06 (broad, 1H, disappeared after D<sub>2</sub>O exchange, -CH<sub>3</sub>-NH-), and 7.86  $\delta$  (broad, 1H, disappeared after D<sub>2</sub>O

exchange,  $\text{CH}_3\text{-NH-}$ ). The structure of (IIIa) was estimated from the appearance of two doublets for  $\text{CH}_3\text{NH}$  and the absence of a singlet due to H at position 5.

The product obtained by the alkaline  $\text{H}_2\text{O}_2$  treatment of (IIIa) was identified with the product, 4-methyl-2-methylamino-5-(N-methylcarbamoyl)thiazole (Va) from the reaction of (VI) and (VII), by the mixed mp, and from UV, Mass, and NMR spectral comparison.

Table I shows the result of monitoring of the thermal rearrangement of (IIa) to (IIIa), by measuring the absorption at 340 nm due to (IIIa) every 2.5 hr in a different solvent.

This result suggests that an essential factor in the rearrangement is the presence of pyridine.

Table I

Solvent	Absorption at 340 nm <sup>b)</sup>	Reflux time (hr)	IIIa Yield (%)	
Cyclohexane	-	30	0	a) Ratio 2:1
Toluene	-	30	0	b) Time required for the
Toluene-pyridine <sup>a)</sup>	> 5 hr	10	80	appearance of the absorp-
Pyridine	> 5 hr	30	90	tion at 340 nm

Scheme 2

The thermal isomerization from (A) to (B) in pyridine shown in the Scheme 2 is summarized in Table II. The effect of substituents, R, R', and R'', was traced by using TLC (ether:2-propanol, 1:1).

Table II

	R	R'	R''	Rearrangement		R	R'	R''	Rearrangement
IIa	CH <sub>3</sub>	CH <sub>3</sub>	CH <sub>3</sub>	+	IIId	H	CH <sub>3</sub>	H	-
IIb	CH <sub>3</sub>		CH <sub>3</sub>	+	IIe <sup>2)</sup>	CH <sub>3</sub>	CH <sub>3</sub>	H	-
IIc	CH <sub>3</sub>		CH <sub>3</sub>	+	IIIf	H	CH <sub>3</sub>	CH <sub>3</sub>	-

There was no rearrangement when R=H as in (IIId) and (IIIf). There was also no rearrangement when R=H as in (IIId) and (IIIf), while the rate of rearrangement was faster when R'=phenyl, as in (IIc), than for (IIa) and (IIb). Therefore, this rearrangement seems to take place when an electron donating group such as CH<sub>3</sub> is present at position 4 in the thiazole ring, with the exception of (IIIf). The reaction mechanism including the roles of 4-CH<sub>3</sub> and of pyridine which is required for the rearrangement is currently under investigation in our laboratory.
