

literature are somewhat divergent (Vesely,⁵ Colerdi and Moe,⁶ Hodgson and Leigh⁷) we synthesized this compound from β -naphthylamine following for the Sandmeyer step the directions of Hodgson and Walker.⁸ The 2-chloro-1-nitronaphthalene so obtained had a melting point of 99–99.5°. The mixed melting point with the sample obtained by the decarboxylation of the 6-chloro-nitro-1-naphthoic acid was 98.5–99°. Accordingly our nitro product must be 6-chloro-5-nitro-1-naphthoic acid.

Nitration of Methyl 6-Chloro-1-naphthoate.—A 9.0-g. sample (0.041 mole) of pure methyl 6-chloro-1-naphthoate (m. p. 66°) was treated with 15 cc. of fuming nitric acid (d. 1.49–1.50) and warmed for five minutes on a water-bath. After cooling, a crystalline mass deposited which was collected on a glass filter and washed with a small portion of cold nitromethane. The crystal mass was already almost white, and after one recrystallization from aqueous methanol, pure methyl 6-chloro-5-nitro-1-naphthoate was obtained: yield, 3.3 g. (30%), m. p. 143.5–144°.

Anal. Calcd. for $C_{12}H_8O_4NCl$: C, 54.23; H, 3.03; N, 5.27; Cl, 13.36. Found: C, 54.52; H, 3.23; N, 5.07; Cl, 13.34.

Hydrolysis of the Nitro Ester.—A solution of 0.5 g. of the ester was refluxed in 30 cc. of 20% aqueous potassium hydroxide, to which 4 g. of salt was added. The substance dissolved after one-half hour of vigorous boiling. In acidification, a dark brown precipitate was obtained. This was filtered and twice recrystallized from nitromethane. Greenish-yellow crystals were obtained which melted at 226.5°. A mixed melting point with 6-chloro-5-nitro-1-naphthoic acid above gave 226–226.5°, showing the identity of the two compounds.

Anilide from the Nitro Acid.—A mixture of 0.2 g. of 6-chloro-5-nitro-1-naphthoic acid and 0.5 cc. of thionyl chloride was refluxed for one-half hour. The reaction mixture was treated with 1 cc. of redistilled aniline and dissolved in 15 cc. of benzene. The yellow suspension was washed with water, with dilute hydrochloric acid, with water and with sodium carbonate solution. After evaporation of the benzene, the residue was recrystallized from aqueous ethanol, using charcoal. The slightly greenish crystalline substance had a melting point of 193–193.5°.

Anal. Calcd. for $C_{17}H_{11}O_3N_2Cl$: C, 62.46; H, 3.40; N, 8.57; Cl, 10.85. Found: C, 62.71; H, 3.30; N, 8.68; Cl, 11.10.

Anilide from the Nitro Ester.—(a) A 0.28-g. sample of the ester was treated with three to four-fold excess of anilinomagnesium bromide for ten minutes on the water-bath. (The anilinomagnesium bromide was prepared by addition of 8 g. of aniline to ethylmagnesium bromide, prepared from 2 g. of magnesium and 10 g. of ethyl bromide in 60 cc. of ether, until the very vigorous evolution of ethane ceased.) Ten cc. of dilute hydrochloric acid was added to the mixture and the ether evaporated at room temperature. The dark brown solid residue from the ether layer was separated from the acidic solution by filtration, and it was recrystallized from aqueous ethanol, yielding 0.12 g. of anilide (34%), m. p. 190–191°. This was recrystallized twice (first with charcoal) to give almost colorless crystals, m. p. 193.5–194°, identical with the anilide obtained from the acid.

(b) When 0.3 g. of the ester was heated with 0.2 g. of aniline at 160–170° for twenty minutes, the ester was recovered unchanged, m. p. 143.5–144°.

Amide from the Nitro Acid.—A 0.22-g. sample of 6-chloro-5-nitro-1-naphthoic acid was heated with 1 cc. of thionyl chloride for twenty minutes. The mixture was poured into 10 cc. of ice-cooled 33% ammonium hydroxide. It was cautiously heated on the water-bath for five minutes, then cooled, filtered and recrystallized from aqueous ethanol, m. p. 207–208°.

Anal. Calcd. for $C_{11}H_7O_3N_2Cl$: N, 11.17. Found: N, 10.70.

9,9-Dibromofluorene and Formation of a Dangerous Skin Irritant

BY JOHN R. SAMPEY AND SCOTT J. CHILDRRESS

The preparation of 9-bromofluorene by direct photobromination¹ suggested the preparation of 9,9-dibromofluorene by the addition of a second mole of bromine under strong irradiation.

A solution of 16 g. of fluorene in 150 ml. of carbon tetrachloride was placed in a 250 ml. Vitreosil Erlenmeyer flask equipped with reflux condenser. By the use of a six-inch mercury arc close to the flask, the contents were heated to reflux while a solution of 2 moles of bromine in 50 ml. more solvent was added dropwise through the condenser in thirty minutes. Anhydrous conditions were assumed by a calcium chloride tube and irradiation continued thirty minutes after the addition. Evaporation of the solvent yielded a light gray crystalline product recrystallized from acetic acid, *n*-heptane or absolute alcohol. The yield was 45% of material melting at 115° (uncor.). The literature value for 9,9-dibromofluorene is 114°.²

Experiments to further identify the 9,9-dibromofluorene were discontinued when two additional workers to those reported previously,³ were stricken with a severe dermatitis which has spread over large areas of the body, and which is responding slowly to medical treatment. Intense itching, pus formation, and considerable swelling of the hands, arms and face accompany the irritation.

The authors acknowledge with pleasure the interest of Dr. E. Emmet Reid.

Nuclear Substituted 9-(4'-Diethylamino-1'-methylbutylamino)-acridines¹

BY E. R. SHEPARD AND H. A. SHONLE²

At the suggestion of the Committee on Medical Research of the OSRD several years ago, the preparation of a series of nuclear substituted acridines was undertaken. They were prepared in order to study clinically the absorption, excretion and metabolic changes which these materials undergo. In addition, it was of interest to inquire further
