(c 1.6), in 78% yield. After deprotection in a standard manner [(1) H₂, Pd(OH)₂/MeOH; (2) NaOH/aqueous MeOH], tetrasaccharide **2**, the glycan part of GD₃, was obtained quantitatively; its ¹H NMR spectrum (500 MHz, D₂O) showed characteristic signals at δ 5.207 (d, *J* = 3.9 Hz, H-1a_α), 4.643 (d, *J* = 7.8 Hz, H-1a_β), 4.504 (d, *J* = 7.8 Hz, H-1b), 2.767 (dd, *J* = 12.5 and 4.6 Hz, H-3d_{eq}²¹), 2.669 (dd, *J* = 12.2 and 4.4 Hz, H-3c_{eq}²¹), 2.052, 2.022 (2 s, 2Ac), and 1.727 (t, *J* = 12 Hz, H-3c_{ax}). On the other hand, debenzoylation followed by acetylation [Ac₂O, pyridine, 4-DMAP] afforded the lactone **18**²² as an inconsequential mixture of positional isomers with respect to the lactonic linkage. The mixture was, without separation, converted into the corresponding trichloroacetimidate **19**²² [(1) piperidine, AcOH/THF; (2) CCl₃CN,²³ DBU/CH₂Cl₂, 62%], which was further reacted with the protected caramide **17**²⁴ [1.0 equiv of TMSOTf, 4A molecular sieves/CHCl₃] to afford the coupled product **20**²² in 32% yield. After deacetylation [NaOMe/MeOH] and saponification [NaOH/aqueous MeOH], GD₃ (**1**) was obtained in 95% yield. The ¹H NMR spectrum (500 MHz, DMSO-*d*₆-D₂O, 50:1) of synthetic **1** was in full agreement with the one reported for the natural sample by Yu et al.²⁵

In summary, the first total synthesis of ganglioside GD₃ was achieved in a highly stereo- and regioselective manner.

Bromochlorofluoromethane and Deuteriobromochlorofluoromethane of High Optical Purity

Thomas R. Doyle and Otto Vogl*

Polytechnic University, 333 Jay Street
Brooklyn, New York 11201

Received July 5, 1989

Bromochlorofluoromethane (**1**) has been of considerable interest for nearly one century because of the chirality engendered by the all-halogen pendant group. Two synthetic approaches have been made to prepare **1**. One method involves the direct separation of racemic **1** into its antipodes. The second method involves the synthesis of optically active intermediates, which then undergo stereoselective reactions in the final steps to prepare optically active **1**.¹⁻³

Hargreaves³ obtained (+)-**1** and (-)-**1** with [α]_D¹⁹ = +0.20° and -0.13° (in cyclohexane) respectively by treating (+)- and (-)-BrClFCCOCH₃ with KOH; **1** was also prepared with an [α]_D¹⁹ of +0.13° (neat) upon complexation of **1** with brucine⁴ and was shown to have an enantiomeric excess of 4.3 ± 1%. The enantiomeric excess was demonstrated by ¹H NMR spectroscopy of a diastereomeric inclusion complex of **1** with a chiral tailor-made cryptophane.⁵ Extrapolation of this rotation value to enantiomeric purity gave a maximum rotation for **1** of α_D²⁵ = +3.0 ± 0.5° and an α₃₆₅²⁵ of +6.2 ± 1°.

We wished to prepare **1** of high enantiomeric purity because of our interest in the synthesis and polymerization of optically active bromochlorofluoroacetaldehyde (**2**) to chiral poly-**2**, a polymer that was expected to have optical activity based on the contribution not only from the chiral bromochlorofluoromethyl

unit attached to the polyacetal main chain but also from the rigid helical polymer chain conformation which causes optical activity based on macromolecular asymmetry.⁶

For the preparation of **2**, we started with 1-chloro-1,2,2-trifluoroethylene and obtained, after a sequence of five synthesis steps, bromochlorofluoroacetic acid (**3**) in about 25% yield.⁷ **3** could be separated into the optical antipodes by fractional crystallization of its strychnine salt from methanol;¹ no melting point.

The determination of the optical purity was attempted by ¹⁹F NMR spectroscopy of the strychnine salt of **3** in nonpolar solvents, but neither the salt nor the salt in the presence of shift reagents (chiral or achiral) gave satisfactory results. However, it was possible to determine the optical purity of **3** by esterification of the acid with borneol and employing ¹⁹F NMR spectroscopy for the determination of the optical purity. The chemical shift of the diastereomeric esters gave fluorine shift values at about -63.8 ppm (relative to fluorotrichloromethane). The ¹⁹F peaks of the diastereomers were separated by 0.13 ppm. The borneol ester of racemic **3** gave a 50/50 integration of the ¹⁹F spectra for the diastereomers.⁷

The plot of the optical rotation as a function of optical purity of **3** (as determined by ¹⁹F NMR spectroscopy of its borneol ester) resulted in a linear relationship. The pure antipode was calculated to have an $[\alpha]^{22}_{\text{D}}$ of $15.5 \pm 0.2^\circ$ (diethyl ether, 6.50 g/dL). The least soluble salt fraction yielded **3** with an $[\alpha]^{22}_{\text{D}}$ of $+10.3^\circ$ (diethyl ether, 6.86 g/dL) (path length 10 mm), and the most soluble salt fraction yielded **3** with an $[\alpha]^{22}_{\text{D}}$ of -6.3° (diethyl ether, 6.17 g/dL) (path length 10 mm). The enantiomeric excess was 66% (83/17 mixture of the (+) antipode) and 42% (29/71 mixture of the (-) antipode), respectively.

The strychnine salt of **3** was thermally decarboxylated in a heterogeneous medium between 100 and 120 °C when ethylene glycol or deuterium oxide was used as the decarboxylation medium; **1** was obtained in 50–70% yield in ethylene glycol and in 30% yield in deuterium oxide. Elemental anal. Calcd for CHBrClF: C, 8.15; H, 0.69. Found: C, 8.19; H, 0.70. NMR: ¹H, 7.35 and 7.95 ppm ($J_{\text{FH}} = 54$ Hz); ¹³C, 84.65 and 98.17 ppm ($J_{\text{FC}} = 304.43$ Hz); ¹⁹F, -80.09 and -80.74 ppm ($J_{\text{FH}} = 54.99$ Hz).

The least soluble strychnine salt of (+)-**3** was decarboxylated in ethylene glycol, and **1** was obtained with an optical rotation of $\alpha^{22}_{\text{D}} = +1.80 \pm 0.04^\circ$ (neat) (path length 1 dm). The most soluble strychnine salt of (-)-**3** after decarboxylation gave **1** with an optical rotation of $\alpha^{22}_{\text{D}} = -0.92 \pm 0.04^\circ$ (neat) (path length 1 dm). When the extrapolated values of Collet⁵ for optical purity ($3.0 \pm 0.5^\circ$) were used, the optical purity of (+)-**1** was 60% and that of (-)-**1** was 31%. Using our determination of the optical purity of **3** by the borneol ester method⁷ and assuming that no racemization had occurred during this decarboxylation procedure of **3** to **1**, we estimate a maximum value of α^{22}_{D} of $2.75 \pm 0.05^\circ$ as the value of the pure antipode of **1** (probably in the range of 2.7° and 3.5°). This value is in good agreement with the value of $\alpha^{25}_{\text{D}} = 3.0 \pm 0.5^\circ$ obtained previously.^{4,5} The extrapolated value of ref 4 and 5 for optically pure **1** has the disadvantage of using **1** with a very low optical excess of the antipodes for the extrapolation.

We have also decarboxylated (-)-**3** (enantiomeric purity 34%) in deuterium oxide and obtained (-)-**1** with a deuterium purity (by ¹⁹F spectroscopy) as high as 96%. The optical rotation of deuterated (-)-**1** was $\alpha^{22}_{\text{D}} = -1.35 \pm 0.05^\circ$, $\alpha^{22}_{365} = -2.35 \pm 0.05^\circ$ (neat, path length 2 mm), which corresponds to the optical rotation of deuterated **1** of $\alpha^{22}_{\text{D}} = -4.0 \pm 0.3^\circ$ or $\alpha^{22}_{365} = 7.0 \pm 0.5^\circ$ for 100% optical purity. NMR: ¹³C, 81.72, 83.22, 84.72, 95.16, 96.66, and 98.17 ppm ($J_{\text{CF}} = 302.97$ Hz and $J_{\text{CD}} = 33.82$ Hz); ¹⁹F, -82.09, -82.18, -82.31 ppm ($J_{\text{FD}} = 8.3$ Hz).

Our results indicate that decarboxylations of the strychnine salts of **3** in protic (deuterio) media result in the formation of **1** with a high degree of selectivity in retention (or inversion) of the configuration. We believe that **1** of 100% optical purity could be obtained by decarboxylation of optically pure **3**; with our present accuracy limit, we can only predict an optical purity of at least 80%.

Acknowledgment. We thank J. Bartus for his assistance in the measurements of the optical rotations and his advice on experimental procedures, Paul Resnick, and Koichi Hatada and his research group for their assistance with the ¹⁹F NMR spectroscopy of the borneol esters. We also appreciate the comments of Mark Green.

Crystal Structure of Holoenolase Refined at 1.9 Å Resolution: Trigonal-Bipyramidal Geometry of the Cation Binding Site

Lukasz Lebioda* and Boguslaw Stec†

Department of Chemistry
University of South Carolina
Columbia, South Carolina 29208
Received July 24, 1989

We have determined and refined, using crystallographic restrained least squares, the structure of the enolase-Zn²⁺ complex at 1.9-Å resolution. The final crystallographic *R* factor was 14.9%, and bond lengths in the molecule have a root-mean-square deviation from ideal values of 0.015 Å. The ligands of the Zn²⁺ cation are all oxygen atoms which form an almost regular trigonal bipyramid with the monodentate carboxylic groups of Asp246 and Asp320 in the axial positions and the monodentate carboxylic group of Glu295 and two water molecules in the equatorial positions. The enolase-Zn²⁺ complex has 80% of the activity of the physiological enolase-Mg²⁺ complex,^{1,2} so it is most probable that the Zn²⁺ and Mg²⁺ complexes are isostructural. The structure of the active ternary complex enolase-Mg²⁺-2-phosphoglycerate/phosphoenolpyruvate also shows a trigonal bipyramid coordination geometry for Mg²⁺ cation. A search through the Cambridge Crystallographic Database³ did not find any all-oxygen trigonal-bipyramidal coordination geometry for Mg²⁺ ion and only two for Zn²⁺ ion. Thus the metal-ion environment in the active site of enolase is unusual and most probably critical for the catalytic process. It can be speculated that five-coordinated Mg²⁺ or Zn²⁺ ions are well suited for participation in enolase catalysis. They should strongly polarize the ligand, the H₂O molecule or the hydroxyl group of 2-phosphoglycerate; on the other hand, the ion environment should be relatively unstable to allow easy dissociation of substrate/product molecules.

The structure of holoenolase is very similar to that of apoenolase,^{4,5} with an average deviation between the main-chain atoms of 0.19 Å and 0.31 Å between the side-chain atoms.

Enolase catalyzes the dehydration of 2-phospho-D-glycerate to phosphoenolpyruvate. All known enolases exhibit an absolute
