

# Total Chemical Synthesis of an Intra-A-Chain Cystathionine Human Insulin Analogue with Enhanced Thermal Stability

John A. Karas, Nitin A. Patil, Julien Tailhades, Marc-Antoine Sani, Denis B. Scanlon, Briony E. Forbes, James Gardiner, Frances Separovic, John D. Wade,\* and Mohammed Akhter Hossain\*

**Abstract:** Despite recent advances in the treatment of diabetes mellitus, storage of insulin formulations at 4 °C is still necessary to minimize chemical degradation. This is problematic in tropical regions where reliable refrigeration is not ubiquitous. Some degradation byproducts are caused by disulfide shuffling of cystine that leads to covalently bonded oligomers. Consequently we examined the utility of the non-reducible cystine isostere, cystathionine, within the A-chain. Reported herein is an efficient method for forming this mimic using simple monomeric building blocks. The intra-A-chain cystathionine insulin analogue was obtained in good overall yield, chemically characterized and demonstrated to possess native binding affinity for the insulin receptor isoform B. It was also shown to possess significantly enhanced thermal stability indicating potential application to next-generation insulin analogues.

**D**iabetes mellitus is a significant global health issue.<sup>[1]</sup> Insulin remains an essential therapeutic for the treatment of type 1 diabetes mellitus and is often used for the treatment of type 2 diabetes.<sup>[2]</sup> Numerous insulin analogues have been developed in the past two decades, both long- and short-acting, with several in clinical use. However, together with native insulin, these all undergo chemical degradation and possess a separate propensity to form amyloid fibrils.<sup>[3]</sup> Both phenomena are accelerated by heat so that insulin formula-

tions require refrigeration. Chemical degradation can manifest itself as de-amidation, oxidation, covalent aggregation and disulfide shuffling and severely impacts upon the formulation and storage of insulin.<sup>[4,5]</sup> This is problematic for patients living in poorer regions with tropical climates where there is often no consistent access to electricity and refrigeration.<sup>[6]</sup> Significant levels of impurities in pharmaceutical preparations can affect dosage and, through covalent aggregates, cause immunological side effects.<sup>[5]</sup> Therefore, development of new insulin analogues with enhanced thermal stability and concomitant increased resistance to chemical degradation is particularly desirable.

A single-chain insulin<sup>[7]</sup> and an analogue with four disulfide bonds<sup>[8]</sup> have each been reported to minimize covalent aggregation through introduction of greater structural stability to the insulin molecule which, in turn, imparts greater thermal stability. Replacement of cystine bonds with stable isosteric bridges<sup>[9,10]</sup> can both prevent S-reduction, disulfide shuffling and polymer formation as well as introduce increased stability although potentially at the risk of loss of functional activity. The efficacy of this approach has been demonstrated in peptides such as oxytocin whereby a selenoether analogue was synthesized and found to have a twenty-fold increase in thermal stability.<sup>[11]</sup> Therefore, the substitution of cystine with non-reducible mimetics shows much promise for improving the shelf life of insulin formulations.

Insulin possesses a complex structure with 51 residues, two chains and three disulfide bonds (Figure 1 A) and is currently produced by recombinant DNA synthesis<sup>[12]</sup> because this enables large quantities of the hormone to be produced which is essential for meeting the huge global demand of pharma-

ceutical preparations. However, novel insulin analogues that need to be produced chemically may be commercially feasible as therapeutics for niche markets (such as in regions where thermal stability is an issue) provided that the synthesis is efficient. There are already precedents for the large scale chemical synthesis of other complex peptide-based active pharmaceutical ingredients.<sup>[13]</sup> Therefore, replacement of the disulfide bonds in insulin with stable isosteres to potentially improve its thermal stability can be viable.

When deciding which disulfide mimetics to use, consideration is given to geometry, toxicity and especially yields since the chemistry should preferably be scalable. Diselenide,<sup>[14]</sup> selenoether,<sup>[11]</sup> triazole,<sup>[15–17]</sup> lactam<sup>[18,19]</sup> and dicarba<sup>[20–22]</sup> bridges have all been employed as cystine isosteres. However a thioether bridge<sup>[22–24]</sup> was preferred because it more closely mimics the disulfide bond in biologically active peptides and proteins. Although an early attempt to incorporate this moiety to substitute for the intra-A-chain disulfide bond of ovine insulin via solution synthesis was briefly reported, only a trace amount of a highly heterogeneous product was obtained that was not chemically or biologically assessed.<sup>[9]</sup> For this reason we undertook to develop an efficient process of producing A-chain cystathionine insulin, A[S-CH<sub>2</sub>] human insulin (Figure 1 B) via solid phase peptide synthesis (SPPS).

The assembly of cystathionine-containing peptides has been studied extensively using *tert*-butyloxycarbonyl (Boc) or 9-fluorenylmethyloxycarbonyl (Fmoc) SPPS protocols. Desulfurization of a disulfide bond is one method available to form the thioether moiety<sup>[25]</sup> although this can lead to loss of chiral integrity of the cysteine  $\alpha$ -carbon. Forming the macrocycle via an S<sub>N</sub>2 reaction between a free thiolate and halogenated side-chain can be performed on the solid support<sup>[26]</sup> or in solution<sup>[11]</sup> but this can be low yielding due to steric hindrance and/or hydrolysis of the halide. Incorporation of pre-formed thioether building blocks with orthogonal protection is used widely<sup>[22,23,27]</sup> and allows macrocyclization to occur via lactamization which is higher yielding. There is the need, however, to synthesize complex building blocks. Alternatively, it is possible to alkylate the free thiol of cysteine with a suitable halogenated amino acid on the solid support.<sup>[28,29]</sup> A variation of the latter method—whereby the nucleophilic attack occurs in the reverse direction—would only require the synthesis of simple monomeric building blocks and avoid the difficulties of the preceding methods. To achieve this, Fmoc-protected  $\gamma$ -bromohomoalanine (Fmoc- $\gamma$ -Br-hAla-OH) was synthesized via a modified version of an existing method (Scheme 1 A).<sup>[26]</sup> A novel cysteine derivative, N <sup>$\alpha$</sup> -mono-methoxytrityl-cysteinyl- $\alpha$ -allyl ester (Mmt-Cys-OAll) was also produced efficiently with suitable orthogonal protecting groups (Scheme 1 B). A similar conceptual approach has recently been reported by Baell and co-workers in a simple cyclic peptide system.<sup>[30]</sup> Our work improves on this with respect to the higher yields of the amino acid precursors and application to forming a lactam within a complex peptidic system. The Fmoc SPPS of A[S-CH<sub>2</sub>] human insulin, containing the homoalaninyl-type residue (or  $\gamma$ -carba moiety) at CysA11, is described herein.

The synthesis of the human insulin A-chain is outlined in Scheme 2. Acylation of the Rink linker via the aspartate side-

**Scheme 1.** A) Reagents and conditions: a) 1 equiv. Fmoc-OSu in pyridine, 4 h; b) HBr/AcOH, 4 h. B) Reagents and conditions: c) 2 equiv. Mmt-Cl, 5 equiv. DIEA in THF, 4 h; d) 2 equiv. tri-*n*-butylphosphine, 10 equiv. H<sub>2</sub>O in THF, 18 h; e) flash chromatography. chain on the solid support was performed to avoid epimerization of asparagine during loading.<sup>[31]</sup> Diphenylmethyl (Dpm)<sup>[32]</sup> was the preferred protecting group for the A20 thiol since there is insufficient chemoselectivity between trityl (Trt) and mono-methoxytrityl (Mmt) removal. After assembly of **I**, acylation of the N-terminus with Fmoc- $\gamma$ -Br-hAla-OH using carbodiimide activation proceeded efficiently (and avoids lactone formation) to generate **II**. Introduction of Mmt-Cys-OAll under basic conditions resulted in nucleophilic attack at the  $\gamma$ -carbon by the thiolate to form the thioether moiety (**III**). After incorporation of residues A7–A10 with acetamidomethyl (Acm) protection at A7 (**IV**), cleavage of the allyl ester with palladium(0) via allylic transfer<sup>[33]</sup> was performed followed by Fmoc removal (**V**). Lactamization was slow, most likely due to steric hindrance on the solid support. Nevertheless, multiple treatments with the acylating reagents to the resin-bound peptide generated **VI**. No significant cross-linking was observed by reversed-phase high performance liquid chromatography (RP-HPLC) or matrix-assisted laser desorption ionization mass spectrometry (MALDI-MS). After treatment with 1% trifluoroacetic acid (TFA) in dichloromethane (DCM) to cleave the Mmt protecting group from the N-terminus,<sup>[34]</sup> residues A1–A5 were incorporated to form **VII**. Cleavage from the solid support and concomitant deprotection with a TFA cocktail, followed by purification using RP-HPLC generated the purified A-chain precursor (**VIII**) in a total yield of 12% relative to crude material.

The B-chain was synthesized using standard Fmoc SPPS protocols and S-Acm derivatization at B7 (**IX**). After purification, the peptide was functionalized with the S-pyridinesulfonyl (S-Pyr) moiety at B19 followed by a second purification to form **X** in 5% overall yield. Asymmetrical combination of A- and B-chain precursors was then undertaken via displacement of the pyridinesulfonyl leaving group with the  $\beta$ -thiolate at A20.<sup>[35]</sup> The synthetic intermediate **XI** was then purified in a yield of 45%. A large excess of elemental iodine was used to efficiently form the final disulfide bond via oxidative cleavage.<sup>[31]</sup> After 45 minutes over 80% of A[S-CH<sub>2</sub>] human insulin was formed (**XII**). Importantly, no oxidation of the thioether moiety to the sulfoxide was detected. A yield of 25% for the final step was

determined post-purification and the total folding yield as calculated from purified B-chain was 11%. Synthetic A[S-CH<sub>2</sub>] human insulin was characterized via analytical RP-HPLC and MALDI-MS. The purity was determined to be > 96% and the molecular mass was measured to be 5792 Da ( $[M+H]^+$ <sub>th.</sub> = 5791). See the Supporting Information for detailed characterization.

A[S-CH<sub>2</sub>] human insulin had the same binding affinity as the native hormone for the insulin receptor isoform B (IR-B) (Figure 2A).<sup>[36]</sup> This indicates that the tertiary structure is largely unchanged despite the substitution of intra-A-chain cysteine with cystathionine. This is supported by the close similarity of the circular dichroism (CD) spectra (Figure 2B) and <sup>1</sup>H NMR spectra (see the Supporting Information) of both the analogue and native insulin. The proportion of  $\alpha$ -helicity<sup>[37]</sup> was, therefore, calculated to be approximately the same (see the Supporting Information). The *in vitro* plasma stability of A[S-CH<sub>2</sub>] human insulin in human serum was maintained after 24 hours (Figure 3A). This is important because even minor modifications of peptides and proteins can render them unstable as slight conformational changes can expose sensitive amide linkages to proteases.<sup>[38]</sup> Both the analogue and native insulin were also incubated at 60°C for 4 days in H<sub>2</sub>O. The thermal stability of the analogue was significantly increased as shown at day 4 ( $p < 0.05$ ). The native

hormone had degraded by almost 70% while A[S-CH<sub>2</sub>] human insulin was correspondingly degraded to an extent of approximately 10% (Figure 3B). Further evaluation is required, such as *in vivo* testing, determination of the heat stability of hexameric forms of the new analogue and tertiary structure elucidation. That A[S-CH<sub>2</sub>] human insulin retains native insulin activity and possesses significant stability against chemical degradation suggests its potential for further development as a therapeutic for type 1 diabetics in developing countries.

In summary, an improved methodology for the efficient solid phase synthesis of cystathionine-containing peptides has been developed. This was achieved using Fmoc SPPS-compatible, orthogonally-protected monomeric building blocks that can be produced in good yield. This strategy was successfully applied to the synthesis of human insulin by incorporating the thioether moiety in place of the A6–A11 cystine bridge followed by formation of the interchain disulfide bonds. For this approach, the “directionality” of the cystathionine bridge can be reversed by incorporating  $\beta$ -bromoalanyl and homocysteinyl based building blocks instead. This methodology can be readily applied to other cysteine-rich peptides and proteins.

**Figure 2.** A) Insulin receptor binding assay (isoform B) for A[S-CH<sub>2</sub>] human insulin ( $IC_{50} = 6.217 \times 10^{-10}$ ) and native insulin ( $IC_{50} = 4.950 \times 10^{-10}$ ),  $n = 3$ . B) Circular dichroism spectra of A[S-CH<sub>2</sub>] human insulin and native human insulin in H<sub>2</sub>O at 25 °C.

**Figure 3.** A) Serum stability assay of A[S-CH<sub>2</sub>] and native human insulins at 37 °C. B) Thermal stability of A[S-CH<sub>2</sub>] and native insulins in H<sub>2</sub>O at 60 °C.

Total Chemical Synthesis of an Intra-A-Chain Cystathionine Human Insulin Analogue with Enhanced Thermal Stability

**Standing the heat:** An efficient synthesis of human insulin containing a non-reducible cystathionine bridge using simple-to-prepare building blocks is reported. A[S-CH<sub>2</sub>] insulin exhibits native binding affinity for insulin receptor isoform B, adopts a similar secondary structure and is relatively stable in human serum in vitro. Thermal stability is improved which enhances its therapeutic potential.
