Keywords: Fráter alkylation; Macrolides; Ring enlargement; Odor and structure; Circular dichroism.

Abstract: TBS-protected iodo alkohols 6 were prepared via Fráter alkylation and applied in the synthesis of optically active macrolides5 and 10. By ring enlargement of cyclodecanone (7) the superposition molecule 5 of two macrocyclic odorants was synthesized and a conformationally fixed tricyclic macrolide11 constructed.

Generating the dianion A by treatment with two equivalents of LDA effectively locks methyl (3R)-(-)-3hydroxybutyrate (1) in an eclipsed conformation, where the lithium atoms are chelated with the lone electron pairs of the oxygens.² An electrophile approaching from the sterically less hindered side gives the *anti* diastereomer with high selectivity (Scheme 1). As a result, these Fráter alkylations^{3,4} offer the opportunity of introducing additional substituents diastereoselectively in chiral building blocks derived from β -hydroxy esters. For instance, Mori *et al.* applied this strategy in their enantioselective synthesis of the potent antiulcerogen (+)-cassiol.⁵

Scheme 1. Fráter alkylation of methyl (3R)-(-)-3-hydroxybutyrate (1)

We became interested in the methylated 3-hydroxybutyrate 2a as chiral building block for the synthesis of (12S, 13R)-(-)-12-methyl-13-tetradecanolide (5), which we regarded as a superposition of (12S)-(-)-12-methyl-13-tridecanolide (3)⁶ and (13R)-(-)-13-tetradecanolide (4),⁷ macrocyclic odorants isolated from essential oils of *Umbelliferae*. (12S)-(-)-12-Methyl-13-tridecanolide (3) possesses a pronounced musk odor that differs from that of the enantiomer by its animalic character and camphoraceous aspects. In contrast, the musk note of (13R)-(-)-13-tetradecanolide (4) is weaker and woody aspects dominate. In our preceding paper⁷ we attributed this effect to a steric hindrance of the 13-methyl group of 4 with the receptor for macrocyclic musk odorants. To support this suggestion, we had the idea of restraining the musk note of 3 by introducing the (13R)-methyl group of 4. Thus, we wanted to synthesize a macrocyclic odorant that smells animalic but not musk-like (Scheme 2).

Scheme 2. (12S)-(-)-12-Methyl-13-tridecanolide (3), (13R)-(-)-13-tetradecanolide (4), and the superposition molecule (12S,13R)-(-)-12-methyl-13-tetradecanolide (5) with contributions to the Cotton effect assigned

Replacing the carcinogenic hexamethylphosphoric triamide of the original procedure³ by 1,3-dimethyl-3,4,5,6-tetrahydro-2-(1*H*)-pyrimidinone (DMPU),⁸(3*R*)-(-)-3-hydroxybutyrate (1) was methylated in 69% yield with 94% de (¹H NMR of **5**) to give **2a**. Protection of the alkylated hydroxy ester **2a** by the *tert*-butyldimethylsilyl group (TBS), reduction with DIBAH, and iodination of the resulting hydroxy function with triphenylphosphine, imidazole (ImH) and iodine furnished the chiral building block **6a** in 54% overall yield. According to our standard sequence⁷ cyclodecanone (**7**) was deprotonated by LDA / DMPU and alkylated with **6a** in 64% yield. Treatment of the alkylation product **8a** with Amberlyst[®] 15 in dichloromethane provided the cyclic enol ether **9a** in 71% yield (Scheme 3).

Due to competitive reactions initiated by oxidation of the C-H bond of the stereocenter cleavage of the enol ether double bond of 12-methyl-11-oxabicyclo[8.4.0]tetradec-1(10)-ene had been unsatisfactory.⁷ Fortunately, the 12,13-dimethyl compound **9a** was less sensitive, and pyridinium chlorochromate (PCC) on Celite[®] as mild and selective reagent⁹ afforded oxo lactone **10a** in 59% yield. The synthesis of **5** was completed by reduction of the tosylhydrazone of **10a** with bis(triphenylphosphine)copper(I) tetrahydridoborate,¹⁰ which proceeded in 51% without isolation of the tosylhydrazone.

Superposition molecule 5 indeed completely lacks the musk note of 3, although the animalic character and the camphoraceous aspects of 3 are markedly present. Instead of the musk odor 5 possesses a woody cedar-like note reminiscent of compound 4. The overall impression is powdery, animalic, cedarwood-like, and slightly camphoraceous.

This certainly confirms our supposition, but the Cotton effect of 5 expected to be negative like that of 4^7 was found to be positive ($\Delta\epsilon + 0.14$). By comparison of macrolides 3, 4 and 5 the contribution of the 12-methyl group was derived as $\Delta\epsilon + 0.40$. This Cotton effect cancels that of the 13-methyl group ($\Delta\epsilon - 0.40$) to give the value for the ring atoms ($\Delta\epsilon + 0.14$). By virtue of the X-ray crystal structure of 13-tridecanolide¹¹ and the observed chiroptical properties,⁷ we assumed the shown conformation of 3 and 4 (Scheme 2) to be favored. In this conformation (Scheme 2) the 12-methyl group of 5 lies on a nodal plane and should not make any contribution

Scheme 3. Stereoselective syntheses of macrolides 5, 10a and 10b by ring enlargement of cyclodecanone (7) with chiral building blocks 6

Scheme 4. Diastereoselective dihydroxylation of 10b and subsequent intramolecular ketalization to 11

P. KRAFT and W. TOCHTERMANN

to the Cotton effect; either the quadrant rule¹² fails, or the contribution stems from an additional conformer. For clarification, we planned to fix C-12 in *gauche* conformation by construction of a tricyclic skeleton.

Intramolecular ketalization is an efficient access to molecules with fixed geometry like the aggregation pheromones (-)-frontalin¹³ and (+)-*exo*-brevicomin.¹⁴ To build up a dioxabicyclo[3.2.1] octane system we wanted to introduce an allyl group as synthetic equivalent for a 2,3-dihydroxypropyl fragment. Fráter alkylation of 1 by allyl bromide gave 2b as starting material in 71% yield with 97% de (¹H NMR of 9b). Following the same sequence, we converted 2b into 6b in 52% overall yield. Alkylation of cyclodecanone with the chiral building block 6b gave in 67% yield 8b that cyclized in 89% yield to 9b upon treatment with Amberlyst[®] 15 in dichloromethane.

The enol ether double bond of **9b** was cleaved chemoselectively in the presence of the allyl group by PCC/ Celite[®] to provide oxo lactone **10b** in 65% yield. Stoichiometric osmylation¹⁵ of **10b** in ether / pyridine (py) and subsequent intramolecular ketalization catalyzed by Amberlyst[®] 15 afforded the tricyclic macrolide **11** with 94% de (¹H NMR of **11**) in 28% isolated yield (Scheme 4). The configuration of **11** was unambiguously established by the presence of a NOE between one methylene proton on C-15 (δ 3.86) and the methine on C-1 (δ 2.10). As predicted by the quadrant rule,¹² the observed Cotton effect of **11** was negative ($\Delta \varepsilon$ -0.16); accordingly, the contribution of the 12-methyl group of **5** is probably due to an additional conformer.¹¹

The stereochemical course of this diastereoselective dihydroxylation was not influenced by asymmetric ligands, *i.e.* $(DHQD)_2$ - or $(DHQ)_2$ -PHAL.¹⁶ Diastereoselective hydroxylation guided by a remote sulfoxide group¹⁷ or sulfoximine group¹⁸ had already been observed, and Weigel *et al.*¹⁹ had suggested that a carbonyl group may disrupt asymmetric dihydroxylation. Therefore, osmate(VI) ester complex **B** (Scheme 4) might explain the observed diastereoselectivity of the dihydroxylation of **10b**.

In summary, the application of alkylated chiral building blocks **6** in our ring enlargement sequence^{6,7} represents a facile and highly stereoselective method for the synthesis of $(\omega, \omega-1)$ -disubstituted macrolides like **5**, **10a** and **10b**. A quaternary stereogenic center at carbon $(\omega-1)$ should be accessible by repeated Fráter alkylation.⁵ Only recently, Yamamoto *et al.* synthesized $(\omega, \omega-2)$ -disubstituted macrolides by ozonolysis of stereospecifically annulated cyclic enol ethers.²⁰ Both strategies of introducing two stereocenters by ring expansion broaden the synthetic access to medium and large ring lactones.²¹

EXPERIMENTAL

IR spectra were recorded on a Perkin-Elmer Paragon 1000 FTIR-spectrometer. $^{1}H/^{13}C$ NMR spectra (reference: TMS int) were taken in CDCl₃ on a Bruker AC 200 P and a Bruker AM 300, respectively. EI (70 eV) and CI (¹BuH) mass spectra were obtained on a Finnigan-MAT 8230 spectrometer. Column chromatography was performed on Baker Silicagel 30–60 µm and analytical TLC on Macherey-Nagel SIL G/UV₂₅₄ plates. Melting points were determined on a Büchi 510 apparatus and are uncorrected. Elemental analyses were performed by the Mikroanalytisches Laboratorium Ilse Beetz, D-96301 Kronach.

Fráter Alkylation of (3R)-(-)-3-Hydroxybutyrate (1)

General Procedure: To a soln of LDA [prepared under argon atmosphere by addition of *n*-butyllithium (124 mL of 1.6 M in *n*-hexane, 198 mmol) at -78 °C to a soln of diisopropylamine (26.0 mL, 198 mmol) in anhydrous THF (200 mL) and stirring at 0 °C for 30 min] cooled to -78 °C was added methyl (3*R*)-(-)-3-hydroxybutyrate (10 mL, 89.3 mmol; 1) within 10 min. When the reaction temp dropped back to -78 °C the halide (98 mmol) and DMPU (30 mL, 248 mmol) was introduced. After stirring at -78 °C for another 15 min and at 0 °C for 45 min, the reaction mixture was poured into cold sat NH₄Cl aq (200 mL) and the aqueous layer extracted with Et₂O (3 × 200 mL). The combined organic extracts were dried with Na₂SO₄ and concentrated to leave a residue, which was purified by distillation or column chromatography to give the alkylated β -hydroxy esters as clear, colorless liquids.

Chemoselective Carbonyl Reduction of 10a to 5

General Procedure: See ref.⁷

(12S,13R)-(-)-12-Methyl-13-tetradecanolide (5). Scale 2.80 mmol, yield 51% (344 mg), hR_f 24 (n-pentane:Et₂O, 50:1); IR (film, cm⁻¹) \tilde{v} 1731 (s, v OC=O),1216 / 1247 (m, v_{as} C-CO-O); ¹H NMR (CDCl₃, ppm) δ 0.88 (d, J = 6.9 Hz, 3H, 12-Me), 1.21 (d, J = 6.2 Hz, 3H, 14-H₃), 1.24–1.47 (m, 16H, 4-H₂–11-H₂), 1.60 (m_c, 1H, 12-H), 1.62 (m_c, 1H, 3-H_b), 1.72 (m_c, 1H, 3-H_a), 2.30 (ddd, J = 14.4, 7.9 and 3.7 Hz, 1H, 2-H_b), 2.41 (ddd, J = 14.4, 9.5 and 3.7 Hz, 1H, 2-H_a), 4.64 (dq, J = 9.9 and 6.2 Hz, 1H, 13-H); minor diastereomer δ 4.95 (13-H, 3%); ¹³C NMR (CDCl₃, ppm) δ 15.75 (q, 12-Me), 18.97 (q, C-14), 22.26 (t, C-11), 24.10 (t, C-3), 24.35 / 24.79 / 25.61 / 25.97 / 26.33 / 26.37 / 30.81 (t, C-4–C-10), 34.42 (t, C-2), 37.78 (d, C-12), 74.68 (d, C-13), 173.46 (s, C-1); MS (EI, %) m/z 240 (7) [M[⊕]], 222 (5) [M[⊕] - H₂O], 211 (11) [M[⊕] - CHO], 196 (76) [M[⊕] - CO₂], 98 (60) [C₇H₁₄[⊕]], 70 (100) [C₅H₁₀[⊕]]; [α]₁¹⁹ -49.7, [α]₅₄₆ -58.4 (c 2.0, CHCl₃); CD (MeCN) Δε +0.14 (212 nm); Anal calcd for C₁₅H₂₈O₂ (240.4), C 74.95, H 11.74; found C 75.00, H 11.67.

Diastereoselective Dihydroxylation of 10b and Ketalization to 11

Procedure: A soln of OsO₄ (300 mg, 1.18 mmol) in Et₂O (30 mL) was added to **10b** (280 mg, 1.00 mmol) in Et₂O (50 mL) containing pyridine (0.2 mL), and the mixture stirred at room temp for 3 h. The supernatant was decanted, the residue dissolved in dichloromethane (80 mL) and treated with 15% NaHSO₃ aq (80 mL, 115 mmol). After stirring at room temp for 14 h, the organic layer was separated and the aqueous extracted with Et₂O (3 × 100 mL). The combined organic extracts were dried with Na₂SO₄, Amberlyst[®] 15 (1.0 g) was added, and the mixture was stirred at room temp for 1 h. The resin was filtered off, the filtrate concentrated under reduced pressure, and the residue purified by column chromatography to provide **11** (82 mg, 28%) as colorless crystals.

Acknowledgement

Thanks are due to Dr. H. Surburg and the perfumers of Haarmann & Reimer GmbH, D-37601 Holzminden, for olfactory evaluation. Special thanks go to Prof. Dr. W. Steglich and Dipl.-Chem. M. Müller, Institut für Organische Chemie der Universität München, for recording the CD spectra, and to Dr. C. Wolff, Universität Kiel, for his kind assistance in NMR assignment problems. – P. K. is most grateful to the Stiftung Stipendien-Fonds des Verbandes der Chemischen Industrie for a grant. In addition, this work was financially supported by the Fonds der Chemischen Industrie. P. KRAFT and W. TOCHTERMANN
