Supporting Information

ABSTRACT: A reinvestigation of cobalt-corrole-triphenylphosphine complexes has yielded an unexpectedly subtle picture of their electronic structures. UV-vis absorption spectroscopy, skeletal bond length alternations observed in X-ray structures, and broken-symmetry DFT (B3LYP) calculations suggest partial Co^{II}-corrole^{•2-} character for these complexes. The same probes applied to the analogous rhodium corroles evince no evidence of a noninnocent corrole. X-ray absorption spectroscopic studies showed that the Co K rising edge of Co[TPC]- (PPh_3) (TPC = triphenylcorrole) is red-shifted by ~1.8 eV relative to the bona fide Co(III) complexes Co[TPC](py)₂ and Co[TPP](py)Cl (TPP = tetraphenylporphyrin, py = pyridine), consistent with a partial Co^{II}-corrole^{•2-} description for Co[TPC](PPh₃). Electrochemical measurements have shown that both the Co and Rh complexes

undergo two reversible oxidations and one to two irreversible reductions. In particular, the first reduction of the Rh corroles occurs at significantly more negative potentials than that of the Co corroles, reflecting significantly higher stability of the Rh(III) state relative to Co(III). Together, the results presented herein suggest that cobalt-corrole-triphenylphosphine complexes are significantly noninnocent with moderate Co^{II}-corrole^{•2-} character, underscoring-yet again-the ubiquity of ligand noninnocence among first-row transition metal corroles.

■ INTRODUCTION

Half a century after the term was coined,¹ noninnocent ligands continue to fascinate inorganic chemists.^{2,3} Not only have important new examples of such ligands emerged in recent years, they have also been recognized for their important role in redox catalysis.⁴ The phenomenon is particularly widespread in the currently fast-developing field of metallocorroles, where a large number of complexes exhibit varying degrees of corrole $^{\circ 2^{-1}}$ character.⁵ Thus, while copper $^{6-15}$ and chloroiron $^{7,16-18}$ corroles were recognized as noninnocent early on, new examples of noninnocent metallocorrole systems such as ${\rm FeNO}^{19,20}$ and ${\rm Fe}_2(\mu\text{-}{\rm O})^{21}$ corroles are also accumulating at a steady rate.²² (Examples of innocent metallocorroles include CrO and MoO corroles,²³ TcO^{24} and ReO^{25} corroles, RuN^{26} and OsN^{27} corroles, and Au^{28-30} corroles.) In this study, we have evaluated the potential noninnocent character of cobalt– corrole–triphenylphosphine $^{31-33}$ complexes and compared them with their rhodium analogues.^{34,35} The question is an important one, because cobalt corroles are of increasing importance in a number of technological applications such as hydrogen evolution from water³⁶⁻³⁸ and ligand sensing.³⁹⁻⁴²

As in a number of other cases, the first inkling that Co-PPh₃ corroles may not be true Co(III) complexes came from their optical spectra. Over a long series of studies, ^{5-7,10-16,19-30} we have established that the Soret absorption maxima of noninnocent meso-tris(para-X-phenyl)corrole (TpXPC) derivatives redshift markedly with increasingly electron-donating character of the para substituent X. The Soret maxima of innocent metallotriarylcorroles, in contrast, do not exhibit such a sensitivity to X. An examination of the literature readily established that the Soret maxima of $Co[TpXPC](PPh_3)$ redshift significantly in response to increasingly electrondonating X groups.^{32,33} Accordingly, we undertook a comprehensive reinvestigation of these complexes, employing UV-vis spectroscopy, electrochemistry, X-ray absorption and emission spectroscopies (XAS, XES), and DFT calculations. For comparison, we also investigated the β -octabrominated cobalt series $Co[Br_8TpXPC](PPh_3)$ and the rhodium series $Rh[TpXPC](PPh_3)$. Together, the results paint a remarkably

Received: July 18, 2017 Published: December 6, 2017 subtle picture of the electronic structure of these complexes, as described below.

RESULTS AND DISCUSSION

A. Synthesis and Proof of Composition. Figure 1 depicts the three series of compounds investigated herein. For the

Figure 1. Complexes investigated in this study.

Co[TpXPC](PPh₃) series, four of the five complexes investigated (X = NO₂, H, Me, and OMe) have been previously reported and were resynthesized for this study.^{32,33} The Co[Br₈TpXPC](PPh₃) series, except for Co[Br₈TPC](PPh₃) (TPC = triphenylcorrole),⁴³ and the Rh[TpXPC](PPh₃) series both consist of new compounds. The synthetic protocols ranged from modifications of literature procedures to essentially new procedures, as described below.

Cobalt insertion into corroles has traditionally been accomplished in alcoholic solvents, particularly methanol, in the presence of an added axial ligand.^{31,32,32,33,44–46} Several of the free-base corroles needed in this study, including H₃[TpXPC] (X \neq CF₃) and all H₃[Br₈TpXPC] ligands, however, were found to be poorly soluble in methanol. The use of THF avoided the solubility problems, and complete Co insertion took place smoothly at 45–50 °C in about 90 min for both the TpXPC and Br₈TpXPC series.

For the rhodium corroles reported here, an essentially new synthetic protocol was devised. A first attempt, inspired by a similar method used by Gray et al.47 for the preparation of iridium-tris(pentafluorophenyl)corrole-PPh₃, involved the reaction of free base triarylcorroles with an excess of [Rh- $(cod)_2Cl]_2$ in refluxing THF under an inert atmosphere and in the presence of excess PPh₃ and dry K_2CO_3 . Except for X = CF₃, however, this procedure failed for all the other free base H₃[TpXPC] ligands. Fortunately, changing the solvent to 2:1 dichloromethane/ethanol and using much smaller quantities of both the metal source (1.5 equiv) and PPh_3 (1 equiv) provided facile access to all four Rh[TpXPC](PPh₃) complexes at room temperature and without any provision for an inert atmosphere. Somewhat similar conditions (albeit with no ethanol) have also been previously used by Collmann et al. for the synthesis of various Rh-corrole-amine complexes.⁴⁸

Proof of purity and composition of the products came from clean thin-layer chromatograms, ESI-MS, fully assigned diamagnetic ¹H NMR spectra, elemental analyses for all new compounds that withstood warming and rigorous drying, and, for three compounds, single-crystal X-ray structures.

B. Single-Crystal X-ray Structures. Because several X-ray structures have already been reported for Co–triarylcorrole– PPh₃ complexes, ^{44–46,53,54} no attempt was made to crystallographically characterize the Co[TpXPC](PPh₃) series. X-ray structures were obtained for the novel β -octabrominated complex Co[Br₈TpCF₃PC](PPh₃), and for two Rh corroles, Rh[TPC](PPh₃) and Rh[TpOMePC](PPh₃). Figure 2 presents graphical representations of the three structures, and Tables 1 and 2 list key crystallographic data and geometrical parameters, respectively. A summary of pertinent structural data from the literature is given in Table 3.

The Co-N and Rh-N bond distances in the structures obtained here are in good accord with literature values (Table 3).⁴⁹ The Co–N distances ($\sim 1.88 \pm 0.01$ Å) are about 0.08– 0.09 Å shorter than the Rh–N distances ($\sim 1.965 \pm 0.01$ Å), which is somewhat smaller than the differences in Shannon-Prewitt ionic radii for the two low-spin M(III) ions (Co, 54.5 Å; Rh, 66.5 Å) 50,51 and in Pyykkö's single-bond covalent radii (Co, 1.11 Å; Rh, 1.25 Å).⁵² Comparison with noncorrole X-ray structures suggests that these discrepancies largely reflect unusually short Rh-N distances in Rh corroles, evidently a result of the sterically constricted nature of the corrole N₄ cavity. Careful examination of the M-N₄, M-C_{a8}, and M-C_{b8} displacements and saddling dihedrals shows that the macrocycle conformation is planar to slightly saddled for the majority of the Co complexes and mildly domed for the Rh complexes (Table 3). Both the Co and Rh corroles, however, exhibit similar M–N₄ out-of-plane distances, \sim 0.26–0.28 Å for Co and $\sim 0.27 - 0.31$ Å for Rh.^{35,45} The crystal packing of the complexes varies; thus, both partially cofacial dimers (e.g., Figure 2b) and unstacked (e.g., Figure 2e) are observed for different complexes.

C. UV–Vis Spectroscopy. By now, the optical criterion for ligand noninnocence, i.e., the sensitivity of the Soret maxima of *meso*-triarylcorrole complexes to the *para* substituents X, is well-established.⁵ The criterion applies well to a variety of Fe and Cu corroles, where the noninnocent character of the corrole ligand has also been established with additional spectroscopic and computational methods. Certain Ag¹⁵ and Pt²² corroles were also recognized as noninnocent *via* this criterion. On the other hand, the Soret maxima of innocent metallotriarylcorroles, are essentially invariant with respect to the *para* substituent X.⁵ Against this backdrop, the optical spectra of the group 9 metallocorroles described here (Figure 3 and Table 4) make for an interesting story.

All three series of metallocorroles investigated here exhibit split or double-humped Soret bands. In the case of Co[TpXPC](PPh₃), the higher energy peak, which corresponds to the overall band maximum, exhibits a strong sensitivity to X, shifting from 371 nm for Co[TpNO₂PC]-(PPh₃) to 399 nm for Co[TpOMePC](PPh₃). In contrast, the Soret maxima of the $Rh[TpXPC](PPh_3)$ are essentially invariant with respect to X. According to the aforementioned optical criterion, these results strongly suggest that the $Co[TpXPC](PPh_3)$ series is noninnocent, with significant Co^{II}-corrole^{•2-} character, whereas the analogous Rh series is innocent, i.e., Rh^{III}-corrole³⁻. Such a scenario is analogous to Cu and Ag¹⁵ triarylcorroles and to FeNO and RuNO²⁶ triarylcorroles; in both of these cases, the first-row transition metal complexes are strongly noninnocent, whereas the secondrow complexes are essentially innocent.

The Soret envelope of the $Co[Br_8TpXPC](PPh_3)$ series is red-shifted by approximately 30 nm relative to the non-

Figure 2. Selected views of X-ray structures. Co[Br₈TpCF₃PC](PPh₃): (a) top and (b) side views. (c) Rh[TpOMePC](PPh₃). Rh[TPC](PPh₃): (d) single molecule and (e) packing diagram.

brominated Co[T*p*XPC](PPh₃) series. Unfortunately, the Soret bands of the brominated complexes consist of two closely spaced humps, which cannot be accurately deconvoluted. It is clear, nevertheless, that the substituent effect of X is relatively muted in the brominated series, relative to the nonbrominated series. A parallel may be drawn to analogous behavior of Fe[T*p*XPC](NO) and Fe[Br₈T*p*XPC](NO); substituent effects on the Soret maxima for the latter series are much more muted than those in the former.^{19,20} As noted before, the lack of substituent sensitivity of the Soret maxima in the brominated series most likely reflects the inability of the *meso*-aryl groups to conjugate with the corrole as a result of the steric constraints imposed by the β-bromines.²⁰ **D. DFT Calculations.**^{56,57} DFT calculations support the above interpretations. Thus, B3LYP/STO-TZP calculations yielded a broken-symmetry spin density profile for Co[TPC]-(PPh₃) ($\langle \hat{S}^2 \rangle = 0.58$), consistent with a Co^{II}-corrole^{•2-} description (Figure 4), as well as a surprisingly small singlet-triplet splitting of only 0.14 eV. (It may be worth adding for the uninitiated reader that these broken symmetry densities are not real and hence do not manifest themselves as peak broadenings in the ¹H NMR spectra; they are nevertheless an excellent and efficient way of visualizing the antiferromagnetically coupled nature of the complexes.) In contrast, analogous calculations on Rh[TPC](PPh₃) yielded only a closed-shell solution as well as a larger singlet-triplet splitting of 0.69 eV, indicating an unambiguous Rh(III) ground state that is energetically well-

separated from potential valence isomers. Not unexpectedly, pure functionals do not yield broken-symmetry solutions for either complex, but the same trend in singlet-triplet energy separation is observed. Thus, BP86 calculations yield singlettriplet energy separations of 0.62 and 1.30 eV for the Co and Rh complexes, respectively.

One flaw of the broken-symmetry B3LYP calculations was that they yielded an overly long Co-P distance of 2.40 Å for Co^{II}-corrole^{•2-}. Inclusion of Grimme's dispersion corrections in the B3LYP calculations or the use of a pure functional, with or without the dispersion correction, yielded realistic Co-P distances of ~2.25 Å. For these reasons, TDDFT simulations of the X-ray absorption spectra of Co[TPC](PPh₃) (and reference compounds) were carried out with the B3LYP functional employing BP86 optimized geometries, as described below.

Regardless of the functional used, the optimized geometry of Co[TPC](PPh₃) revealed small but unmistakeable skeletal bond length alternations in the bipyrrole half of the macrocycle, a structural feature that has recently been recognized as a characteristic of corrole^{•2-} radicals.⁵ Remarkably, a previously reported crystal structure of Co[TPC](PPh₃) also shows clear

evidence of such bond length alternation (Figure 5), lending

credence to partial Co^{II}-corrole^{•2-} character for the complex. **E. Electrochemistry**.⁵⁸ Table 5 lists the redox potentials for the various complexes studied, and Figure 6 depicts two representative cyclic voltammograms. All the complexes exhibit two reversible oxidations and one to two irreversible reductions in CH₂Cl₂ with 0.1 M TBAP. The redox potentials of the Co[Br₈TpXPC](PPh₃) series are generally about 450 mV upshifted relative to those of the $Co[TpXPC](PPh_3)$ series. The $Co[TpXPC](PPh_3)$ and $Rh[TpXPC](PPh_3)$ series exhibit similar oxidation potentials, but significantly different reduction potentials, with the Rh complexes undergoing reduction at some 400 mV more negative potentials. The irreversibility of the reductions may be reasonably attributed to the dissociation of PPh₃ from the M(II) reduced state, *i.e.*, $\{M^{II}[TpXPC]\}^{-.59}$ The fact that the Co complexes are substantially easier to reduce than their Rh analogues is consistent with the greater accessibility of the Co(II) state,⁶⁰ consistent with the DFT results described above.

F. X-Ray Absorption Spectroscopy.^{61–63} Cobalt K-edge XAS data were obtained for Co[TPC](PPh₃) and compared with those of the presumptive bona fide Co(III) complexes $Co[TPC](py)_2$ and $Co[TPP](py)Cl^{64}(TPP = tetraphenylpor$ phyrin, Figure 7). The metal K-edge (rising edge) energy position is generally a good indicator of the charge on the absorbing metal ion.⁶⁵ Figure 7 (top inset) shows that the rising edge inflection point occurs at 7718.2, 7720.0, and 7720.4 eV for Co[TPC](PPh₃), Co[TPP](py)Cl, and Co[TPC](py)₂, respectively. The rising-edge region reflects transitions to states that are higher in energy than both Co 3d based orbitals and low-lying ligand orbitals that participate in back-bonding interactions with Co 3d orbitals. Therefore, this region is not directly affected by the field strength exerted by the ligands and is dominated by changes in charge on the metal ion. The sharp increase (>1.8 eV) in the rising-edge energy on going from Table 3. Comparison of Key Distances (Å) and Dihedrals $(\chi_1 - \chi_3)$ for Co/Rh–Corrole–PPh₃ Complexes Reported in the Literature

Co[TPC](PPh₃) to Co[TPP](py)Cl and Co[TPC](py)₂ is indicative of a higher positive charge on the Co atom in the latter two complexes. It is important to note, however, that the rising-edge energy is also affected by structural factors such as long-range multiple scattering, ligand type, structural changes due to changes in the metal spin state (high-spin versus lowspin), metal-ligand distances, etc. In particular, a high-atomicnumber ligand tends to shift the rising edge to lower energies. Thus, the large 2.2-eV shift between Co[TPC](PPh₃) and $Co[TPC](py)_2$ is at least partially attributable to the presence of a heavier axial ligand in $Co[TPC](PPh_3)$. For an evaluation of metal oxidation state, a better comparison is provided by Co[TPC](PPh₃) and Co[TPP](py)Cl, both of which have a third-period axial ligand. The 1.8 eV downshift of the rising edge in Co[TPC](PPh₃), relative to Co[TPP](py)Cl, thus is consistent with a lower positive charge on the Co center in the former complex.

The Co K-pre-edge region, which arises from electric-dipoleforbidden, quadrupole-allowed $1s \rightarrow 3d$ transitions, affords important information about the metal site symmetry and the

ligand field strength.⁶⁶ The expanded pre-edge region (bottom inset, Figure 7) shows that pre-edge intensity weighted average energy (IWAE) values of Co[TPP](py)Cl and Co[TPC](py)₂ are at 7710.2 and 7709.9 eV, whereas the corresponding value for Co[TPC](PPh₃) is 7709.7 eV. These data indicate either a slight weakening of the ligand field or a lower charge on the Co center. The overall ligand field is expected to be weaker for

Inorganic Chemistry

Figure 7. Normalized Co K-edge XAS spectra of $Co[TPC](PPh_3)$ (black), Co[TPP](py)Cl (blue), and $Co[TPC](py)_2$ (red). The top inset depicts the first derivative spectra, where the first inflection points of the rising edge region are marked with an asterisk. The bottom inset shows the expanded pre-edge region.

 $Co[TPC](PPh_3)$, which has only five ligands relative to six in $Co[TPC](py)_2$ and Co[TPP](py)Cl, but the shift in pre-edge energy position is likely to reflect a combination of weakening ligand field and a decrease in the charge on the Co center (as indicated by the shift of the rising-edge postion to lower energies).

G. X-Ray Emission Spectroscopy.^{67,68} To determine the electronic structure of Co[TPC](PPh₃) with greater certainty, we carried out comparative Co $K\beta$ XES measurements on Co[TPC](PPh₃), Co[TPC](py)₂, and Co[TPP](py)Cl as well as the Co(II) complex Co[TPP].⁶⁹ The spectra consist of the Co $K\beta_{1,3}$ and the Co $K\beta'$ features, with the Co $K\beta'$ feature gaining intensity *via* 3p-3d exchange interactions. These features are strongly influenced by the number of unpaired electrons at the Co center.⁷⁰ In the case of S = 1/2 Co(II), the unpaired 3d electron results in a small increase in the Co $K\beta'_{1,3}$ feature, as may be seen for Co[TPP] in Figure 8, thus affording a means for distinguishing between S = 1/2 Co(II) and S = 0 Co(III).⁷¹

Figure 8 shows that the Co $K\beta_{1,3}$ emission spectrum of Co[TPP] consists of a distinct, asymmetric feature with a maximum at 7649.8 eV. The asymmetry results from a low-lying $K\beta'$ feature due to the presence of an unpaired electron at

Figure 8. Normalized Co K-edge XES spectra of Co[TPC](PPh₃) (black), Co[TPP](py)Cl (blue), Co[TPC](py)₂ (red), and Co[TPP] (light green). The top inset shows the expanded $K\beta_{1,3}$ region, and the bottom inset shows the expanded $K\beta_{valence}$ region.

the Co center. In contrast, the complexes Co[TPC](PPh₃), Co[TPC](py)₂, and Co[TPP](py)Cl all exhibit symmetric spectra with maxima at 7648.9, 7649.0, and 7649.1 eV, respectively, suggestive of a Co(III)-like ground state. A comparison of the $K\beta_{valence}$ region (bottom inset, Figure 8) reflects large differences in metal–ligand interactions among the four complexes, consistent with differences in both ligand type and coordination number.⁷²

The apparent discrepancy between XAS rising-edge shift and the energy of the XES $K\beta_{1,3}$ feature can be explained on the basis of covalent interactions between the Co and the ligands and the influence of delocalization of Co 3d character into the ligand orbitals, which in turn can influence the energy position of the XES spectra. Recently, DeBeer et al. have demonstrated that metal-ligand covalence can have a significant influence on the splitting between the $K\beta'$ and the $K\beta_{1,3}$ features,⁷³ especially if it leads to significant reduction in metal character in the primarily metal d-based orbitals. This conclusion was reached on the basis of an analysis of a series of Fe complexes for which a significant redshift of the $K\beta_{1,3}$ feature was observed on going from the relatively ionic $[FeF_6]^{3-}$ to the much more covalent $[Fe(SR)_4]^-$ complex.

For a low-spin S = 0 Co(III) species, the $K\beta' - K\beta_{1,3}$ splitting is 0 eV, since there is no metal 3p–3d exchange interaction. For low-spin Co(II), this splitting is given by $e^2(4G_1 + 42G_3)$, where e^2 is the Stevens orbital reduction factor for the e_g orbitals and $4G_1 + 42G_3$ is the Co p–d exchange interaction energy per spin pair, which has been calculated to be 7.425 eV for a free Co(II) ion (see Table S16, ref 73). In order to obtain the Stevens orbital reduction factors, DFT calculations were carried out on Co[TPC](PPh_3), Co[TPC](py)₂, Co[TPP]-(py)Cl, and [Co(TPP)], as detailed in the Experimental Section. TDDFT calculations were also carried out for the Co 1s \rightarrow 3d transitions and were found to yield a reasonably good simulation of the experimental Co K pre-edge XAS spectra, as shown in Figure 9.

Figure 9. Comparison of TDDFT 1s \rightarrow 3d spectra (dotted lines) with the experimental Co K pre-edge XAS data (solid lines) for Co[TPC](PPh₃) (black), Co[TPP](py)Cl (blue), Co[TPC](py)₂ (red), and Co[TPP] (light green).

The above experimentally calibrated DFT calculations provided the Co 3d contributions to the e_g orbitals via the Löwdin method and thereby also the Stevens orbital reduction factors (Table 6). Table 6 shows that both the d_z^2 and $d_x^2-y^2$ orbitals engage in covalent interactions with the TPP and TPC ligands and that the interaction is especially strong for Co[TPC](PPh₃), leading to greater reduction in its calculated

Table 6. Stevens Reduction Factors (e) Obtained from the Sum of the DFT Löwdin d Populations

	Co[TPP]	Co[TPC] (py) ₂	Co[TPP](py) Cl	Co[TPC] (PPh ₃)
$(\alpha + \beta) 3d_{z^2}$	155.8	124.3	127.5	83.2
$(\alpha + \beta) 3d_{x^2-y^2}$	139.0	123.7	127.3	109.3
total	294.8	248.0	254.7	192.5
e ²	0.54	0.38	0.41	0.23
ΔE^{a} (eV)	4.2			1.8

 ${}^{a}\Delta E$ is calculated by using the calculated Co p-d exchange interaction energy of 7.425 eV and is calculated for the low-spin d⁷ species.

e² value. Like the remainder of our studies, these calculations thus also ascribe significant Co^{II}-corrole^{•2-} character to the Co[TPC](PPh₃) complex. A hypothetical and simplistic view of $Co[TPC](PPh_3)$ as purely Co^{II} -corrole^{•2-} and an e² value of 0.23 leads to a calculated $K\beta' - K\beta_{1,3}$ splitting of 1.8 eV, which is 2.4 V lower than that of Co[TPP] and consistent with the observed blueshift of $K\beta_{1,3}$ feature of the latter complex. Since the $K\beta'$ feature is weak for low-spin d⁷ species and weakens further and crawls under the main $K\beta_{1,3}$ feature with increased metal-ligand covalence, an experimental estimation of ΔE is difficult. The ~0.9 eV shift between the $K\beta_{1,3}$ features of [Co(TPP)] and [Co(TPC)]PPh₃, however, may be viewed as reasonably consistent with theory, as it is just under half the calculated value of 2.4 eV. In other words, even if Co[TPC]-(PPh₃) were a full-fledged Co^{II}-corrole $^{\bullet 2-}$ species, its main $K\beta_{1,3}$ feature should be significantly red-shifted relative to Co[TPP] because of strong metal-ligand covalence in Co[TPC](PPh₃). Thus, although the XES data are not diagnostic of the Co oxidation state in Co[TPC](PPh₃), they are consistent with a highly covalent electronic structure with partial Co^{II}-corrole^{•2-} character and thus also with the XAS data.

A multitechnique reinvestigation of cobalt-corrole-triphenylphosphine complexes has suggested that they are not true Co(III) complexes, as long supposed, but are noninnocent with partial Co^{II}-corrole^{•2-} character. Thus, the Soret maxima of Co[TpXPC](PPh₃) redshift markedly with increasing electrondonating character of the meso-aryl para substituent X, a key signature of corrole radical states. In contrast, the Soret maxima of $Rh[TpXPC](PPh_3)$ are essentially invariant with respect to the para substituent X, indicating an innocent Rh^{III}-corrole³⁻ description. This argument is supported by DFT B3LYP calculations on Co[TPC](PPh₃), which yielded a brokensymmetry ground-state spin density profile consistent with a Co^{II}-corrole^{•2-} description as well as a singlet-triplet gap of only 0.15 eV. In contrast, analogous calculations on Rh[TPC]-(PPh₃) yielded a fully spin-paired ground state and a much higher singlet-triplet gap of 0.94 eV. Skeletal bond length alternations in the X-ray structure of Co[TPC](PPh₃) (but not the analogous Rh complexes) are also suggestive of a corrole radical. XAS measurements also revealed that the Co K rising edge of Co[TPC](PPh₃) is some 1.8 eV lower than those of the presumptive, genuine Co(III) complexes Co[TPP](py)Cl and $Co[TPC](py)_2$, consistent with a lower positive charge on the metal in Co[TPC](PPh₃). In apparent contrast to these findings, Co[TPC](PPh₃), Co[TPC](py)₂, and Co[TPP](py)Cl were all found to exhibit near-identical $K\beta_{1,3}$ emission maxima that are red-shifted by 0.8 ± 0.1 eV relative to

Co[TPP]. DFT calculations provided a rationale for this paradox in terms of a high degree of metal-ligand covalence in Co[TPC](PPh₃) relative to the other compounds. These results emphasize that spin state assignments based simply on the energy of the $K\beta_{1,3}$ feature may be erroneous, especially for highly covalent systems such as Co[TPC](PPh₃).

EXPERIMENTAL SECTION

Materials. All reagents and solvents were used as purchased unless otherwise noted. CHROMASOLV HPLC-grade n-hexane and dichloromethane were used as solvents for column chromatography. Silica gel 150 (35–70 μ m particle size, Davisil) was used as the stationary phase for flash chromatography, and silica gel 60 preparative thin-layer chromatographic (PTLC) plates (20×20 cm, 0.5 mm thick, Merck) were used for final purification of the products. Triphenylphosphine was recrystallized from hot methanol and stored under nitrogen. Cobalt(II) acetate tetrahydrate, Co(OAc)₂·4H₂O, obtained from Merck, and bis[chloro(1,5-cyclooctadiene)rhodium(I)], [Rh-(cod)₂Cl]₂, obtained from Sigma-Aldrich, were both used as received. Anhydrous dichloromethane for electrochemistry was prepared by distillation after predrying with CaH₂ and stored over 3 Å molecular sieves. The starting materials, the free base corroles H₃[TpXPC] and free base β -octabromocorroles H₃[Br₈TpXPC] (X = CF_3 , H, Me, OMe), were synthesized as previously reported.⁷⁴

Instrumentation. Ultraviolet-visible spectra were recorded on an Agilent Cary 8454 UV-visible spectrophotometer in CH₂Cl₂. Cyclic voltammetry experiments were performed with an EG&G Princeton Applied Research Model 263A potentiostat equipped with a threeelectrode system consisting of a glassy carbon working electrode, a platinum wire counterelectrode, and a saturated calomel reference electrode (SCE). Tetrakis(n-butyl)ammonium perchlorate (Sigma-Aldrich, TBAP), recrystallized three times from absolute ethanol, vacuum-dried at 40 °C for 2 days, and kept in a desiccator for further drying for at least 2 weeks, was used as the supporting electrolyte. The reference electrode was separated from bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. All potentials were referenced to the SCE. A scan rate of 100 mV/s was used. The anhydrous dichloromethane solutions were purged with argon for at least 5 min prior to electrochemical measurements, and an argon blanket was maintained over the solutions during the measurements. ¹H NMR spectra were recorded on a 400 MHz Bruker Avance III HD spectrometer equipped with a 5 mm BB/¹H $(BB = {}^{19}F, {}^{31}P - {}^{15}N)$ SmartProbe in CDCl₃ and referenced to residual CHCl₃ (7.26 ppm), all at room temperature. High resolution electrospray ionization (HR-ESI) mass spectra were recorded on an LTQ Orbitrap XL spectrometer.

Synthesis of Cobalt–Triarylcorrole–Triphenylphosphine Complexes. A detailed procedure is described below for the synthesis of cobalt–tris(4-trifluoromethylphenyl)corrole–triphenylphosphine, $Co[TpCF_3PC](PPh_3)$. A similar procedure was also followed for the synthesis of the other Co complexes, except for details of the chromatographic purifications, which are specified separately. Cobalt corroles with electron-donating para substituents (X = Me and OMe) were found to be somewhat unstable in contact with the silica gel used for column chromatography, which may have led to comparatively lower yields for these complexes.

Synthesis of Co[TpCF₃PC](PPh₃). To a THF solution (10 mL) of free-base tris(4-trifluoromethylphenyl)corrole (0.025 g, 0.034 mmol) in a 25-mL round-bottomed flask was added Co(OAc)₂·4H₂O (5 equiv, 0.042 g, 0.17 mmol) and NaOAc (15 equiv, 0.042 g, 0.51 mmol), and the resulting solution was stirred at room temperature for 5 min. Triphenylphosphine (5 equiv, 0.045 g, 0.17 mmol) was then added, and stirring was continued at 45 °C for 90 min, during which the color of the solution turned from green to dark red. After removal of the solvent by rotary evaporation, the dark residue obtained was chromatographed on a silica gel column (height 12 cm) with 5:1 *n*-hexane/dichloromethane as eluent. The product eluted as an intense, dark red band, which was collected and evaporated to dryness. The resulting solid was further purified by PTLC using 3:1 *n*-hexane/

CH₂Cl₂ as eluent. The front red band consisted of pure Co-[TpCF₃PC](PPh₃) (0.029g, 81%). UV-vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 385 (5.76), 411 (sh, 4.84), 560 (1.19). ¹H NMR (CDCl₃, 25 °C): δ 8.73 (d, J = 4.4 Hz, 2H, β -pyrrolic), 8.36 (d, J = 4.8 Hz, 2H, β -pyrrolic), 8.20 (br s, 2H, meso-aryl), 8.12 (s, 1H, meso-aryl), 8.10 (d, J = 4.8 Hz, 2H, β -pyrrolic), 8.03 (d, J = 4.4 Hz, 2H, β -pyrrolic), 7.93–7.85 (m, 5H, meso-aryl), 7.82 (d, J = 8.04 Hz, 1H, meso-aryl), 7.12–7.06 (br s, 2H, meso-aryl), 7.41 (d, J = 7.96 Hz, 1H, meso-aryl), 7.12–7.06 (m, 3H, p-H of PPh₃), 6.75–6.67 (m, 6H, m-H of PPh₃), 4.68–4.60 (m, 6H, o-H of PPh₃). HRMS (major isotopomer) [M]⁺: 1048.1788 (exptl), 1048.1782 (calcd). Elemental analysis found (calcd): C, 66.58 (66.42); H, 3.72 (3.36); N, 5.19 (5.34).

Synthesis of Co[TpMePC](PPh₃). Silica gel column chromatography with *n*-hexane/CH₂Cl₂ (3:2) as eluent afforded 0.026 g (0.029 mmol, 66%) of Co[TpMePC](PPh₃). UV-vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 392 (5.33), 563 (0.99). ¹H NMR (CDCl₃, 25 °C): δ 8.57 (d, J = 4.4 Hz, 2H, β -pyrrolic), 8.33 ((d, J = 4.76 Hz, 2H, β -pyrrolic), 8.10 (d, J = 4.76 Hz, 2H, β -pyrrolic), 8.03 (d, J = 4.4 Hz, 2H, β -pyrrolic), 8.03 (d, J = 4.4 Hz, 2H, β -pyrrolic), 8.03 (d, J = 7.7 Hz, 1H, *meso*-aryl), 7.50–7.32 (m, 8H, *meso*-aryl), 7.27 (s, 1H, *meso*-aryl), 7.07–7.00 (m, 3H, p-H of PPh₃), 6.74–6.66 (m, 6H, *m*-H of PPh₃), 4.77–4.69 (m, 6H, *o*-H of PPh₃), 2.57 (s, 6H, 5,15-Me), 2.56 (s, 3H, 10-Me). HRMS (major isotopomer) [M]⁺: 886.2630 (exptl), 886.2630 (calcd).

Synthesis of Co[TpOMePC](PPh₃). Silica gel column chromatography with *n*-hexane/CH₂Cl₂ (1:1, then 1:2) as eluent afforded 0.0225 g (0.024 mmol, 59%) of Co[TpOMePC](PPh₃). UV-vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 399 (7.13), 565 (1.27). ¹H NMR (CDCl₃, 25 °C): δ 8.58 (d, J = 4.4 Hz, 2H, β -pyrrolic), 8.34 (d, J = 4.76 Hz, 2H, β -pyrrolic), 8.11 (d, J = 4.76 Hz, 2H, β -pyrrolic), 8.04 (d, J = 4.4 Hz, 3H, overlapping β -pyrrolic and *meso*-aryl), 7.91 (d, J = 7.9 Hz, 1H, *meso*-aryl), 7.51 (s, 2H, *meso*-aryl), 7.29 (d, J = 7.8 Hz, 1H, *meso*-aryl), 7.20-6.99 (m, 10H, overlapping *meso*-aryl and *p*-H of PPh₃), 6.75-6.65 (m, 6H, *m*-H of PPh₃), 4.79-4.66 (m, 6H, *o*-H of PPh₃), 4.01 (s, 6H, 5,15-OMe), 4.0 (s, 3H, 10-OMe). HRMS (major isotopomer) [M]⁺: 934.2475 (exptl), 934.2478 (calcd).

Synthesis of Cobalt– β -Octabromocorrole–Triphenylphosphine Complexes. A detailed procedure is described below for Co[Br₈T*p*CF₃PC](PPh₃); the other β -octabromocorrole complexes were synthesized via a similar protocol, except for the chromatographic purification, which is indicated separately for each complex. Accurate elemental analyses could not be obtained for these complexes because of decomposition on warming and rigorous drying and/or storage.

Synthesis of Co[Br₈TpCF₃PC](PPh₃). To a THF (10 mL) solution of free-base H₃[Br₈TpCF₃PC] (0.025g, 0.018 mmol) in a 50-mL round-bottomed flask was added 5 equiv of Co(OAc)2.4H2O (0.022 g, 0.09 mmol) and 5 equiv of triphenylphosphine (0.024g, 0.09 mmol), and the solution was stirred at 50 °C temperature while open to the atmosphere. The progress of the reaction was monitored by UV-vis spectroscopy and mass spectrometry. After 30-35 min, the solvent was removed by rotary evaporation, and the dark brown residue was chromatographed on a silica gel column with 4:1 nhexane/dichloromethane as eluent. The product eluted as a reddishbrown band, which was collected and evaporated to dryness. Final purification was carried out with PTLC using 7:3 n-hexane/CH₂Cl₂ as eluent. The front brownish-yellow band contained pure product $Co[Br_8TpCF_3PC](PPh_3)$ (0.025g, 82%). UV–vis $(CH_2Cl_2) \lambda_{max} [nm, m_2]$ $\varepsilon \times 10^{-4} (M^{-1} cm^{-1})]$: 396 (5.82), 421 (5.94), 579 (1.49). ¹H NMR $(CDCl_3, 25 \ ^{\circ}C): \delta 7.99 \ (d, J = 7.9 \ Hz, 1H, meso-aryl), 7.94 \ (d, J = 8.0)$ Hz, 2H, meso-aryl), 7.78-7.75 (m, 6H, meso-aryl), 7.39 (d, J = 7.9 Hz, 1H, meso-aryl), 7.27-7.22 (m, 3H, p-H of PPh₃), 7.07 (d, J = 8.2 Hz, 2H, meso-aryl), 6.92-6.85 (m, 6H, m-H of PPh3), 4.87-4.79 (m, 6H, o-H of PPh₃). HRMS (major isotopomer) [M]⁺: 1679.4540 (exptl), 1679.4554 (calcd).

Needle-shaped X-ray quality crystals were obtained by slow diffusion of MeOH vapor into a concentrated $CHCl_3$ solution of the complex over 1 week.

Synthesis of Co[Br₈TPC](PPh₃). Silica gel column chromatography with 3:1 *n*-hexane/CH₂Cl₂ followed by PTLC with 2:1 *n*hexane/CH₂Cl₂ as eluent afforded pure Co[Br₈TPC](PPh₃) (0.018 g, 0.012 mmol, 56%). UV–vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 407 (6.22), 412 (6.29), 584 (1.60). ¹H NMR (CDCl₃, 25 °C): δ 7.85 (d, J = 7.7 Hz, 1H, meso-aryl), 7.81 (d, J = 7.6 Hz, 2H, meso-aryl), 7.71–7.63 (m, 3H, meso-aryl), 7.60–7.46 (m, 6H, meso-aryl), 7.33 (d, J = 7.6 Hz, 1H, meso-aryl), 7.25–7.18 (m, 3H, p-H of PPh₃), 7.01 (d, J = 7.6 Hz, meso-aryl), 6.92–6.86 ((m, 6H, m-H of PPh₃), 4.95–4.87 (m, 6H, o-H of PPh₃). HRMS (major isotopomer) [M]⁺: 1475.4889 (exptl), 1475.4931 (calcd).

Synthesis of Co[Br₈TpMePC](PPh₃). Silica gel column chromatography with 3:1 *n*-hexane/CH₂Cl₂ followed by PTLC with 2:1 *n*-hexane/CH₂Cl₂ as eluent afforded pure Co[Br₈TpMePC](PPh₃) (0.02 g, 0.013 mmol, 62%). UV-vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 418 (5.94), 583 (1.58). ¹H NMR (CDCl₃, 25 °C): δ 7.71 (d. *J* = 7.6 Hz, 1H, *meso*-aryl), 7.67 (d, *J* = 7.6 Hz, 2H, *meso*-aryl), 7.40–7.27 (m, 6H, *meso*-aryl), 7.22–7.16 (m, 4H, *meso*-aryl and *p*-H of PPh₃) overlapping), 6.92–6.84 (m, 8H, overlapping *meso*-aryl and *m*-H of PPh₃), 4.94–4.86 (m, 6H, *o*-H of PPh₃), 2.61 (overlapping s, 9H, 5,10,15-Me protons). HRMS (major isotopomer) [M]⁺: 1517.5397 (exptl), 1517.5402 (calcd).

Synthesis of Co[Br₈TpOMePC](PPh₃). Silica gel column chromatography with *n*-hexane/CH₂Cl₂ (2:3, then 1:2) followed by PTLC with 1:3 *n*-hexane/CH₂Cl₂ as eluent afforded pure Co-[Br₈TpOMePC](PPh₃) (0.023 g, 0.0146 mmol, 73%). UV-vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M^{-1} cm⁻¹)]: 393 (sh, 5.14), 423 (6.49), 584 (1.72). ¹H NMR (CDCl₃, 25 °C): δ 7.74–7.65 (m, 3H, *meso*-aryl), 7.24–7.17 (m, 4H, *meso*-aryl and *p*-H of PPh₃ overlapping), 7.13–7.02 (m, 6H, *meso*-aryl), 6.93–6.85 (m, 8H, overlapping *meso*-aryl and *m*-H of PPh₃), 4.93–4.85 (m, 6H, *o*-H of PPh₃), 4.02 (overlapping s, 9H, 5,10,15-OMe). HRMS (major isotopomer) [M]⁺: 1565.5242 (exptl), 1565.5250 (calcd).

Synthesis of Co[TPC](py)2. A 50-mL round-bottomed flask equipped with a magnetic stir bar was charged with free-base triphenylcorrole (0.03 g, 0.057 mmol) dissolved in pyridine (10 mL). To this solution was added Co(OAc)2.4H2O (0.142 g, 0.57 mmol). The reaction flask was then fitted with a reflux condenser and heated on an oil bath at 100 $^\circ C$ with stirring for 25–30 min. Completion of the reaction was confirmed by UV-vis spectroscopy and mass spectrometry. Upon cooling, the solution was rotary evaporated under a high vacuum to yield a dark greenish-brown residue. The residue was redissolved in a minimum volume of dichloromethane containing a couple of drops of pyridine and was chromatographed on a silica gel column (length 10 cm) with 1:1:0.02 *n*-hexane/dichloromethane/pyridine as eluent. The intense green front running band was collected and identified as the title compound. Recrystallization from a mixture of 3:1 n-hexane/DCM with a few drops of pyridine afforded the pure product (0.0326 g, 0.044 mmol, 77%). UV–vis (CH₂Cl₂) λ_{max} [nm, $\epsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 388 (10.35). UV-vis (CH₂Cl₂, 0.5% pyridine) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 437 (6.86), 452 (6.03), 582 (0.95), 623 (3.09). ¹H NMR (benzene- d_{6} , 25 °C): δ 9.05 (d, J = 4.3 Hz, 2H, β -pyrrolic), 8.93 (d, J = 4.6 Hz, 2H, β-pyrrolic), 8.76–8.70 (m, 4H, β-pyrrolic), 8.40–8.35 (m, 4H, 5,15-o/m-aryl), 8.30-8.25 (m, 2H, 10-o/m-aryl), 7.53-7.41 (m, 9H, 5,15, and 10-o/m/p-aryl), 5.08 (s, 2H, p-H of pyridine), 4.54 (s, 4H, m-H of pyridine), 3.18 (broad-s, 4H, o-H of pyridine). HRMS (major isotopomers in the presence of a drop of pyridine, M = $C_{37}H_{23}N_4Co$: $[M]^+$ (0.70) 582.1225 (exptl), 582.1249 (calcd); [M +py]⁺ (1.00) 661.1676 (exptl), 661. 1671 (calcd); $[M + 2 py]^+$ (0.30) = 740.2100 (exptl), 740.2093 (calcd).

Synthesis of Rhodium–Corrole–Triphenylphosphine Complexes. A detailed procedure is described below for the synthesis of the rhodium–tris(4-trifluoromethylphenyl)corrole–triphenylphosphine complex, Rh[TpCF₃PC](PPh₃). A similar procedure was also followed for the synthesis of the other Rh complexes, except for the optimum methods for chromatographic purifications, which are specified separately.

Synthesis of $Rh[TpCF_3PC](PPh_3)$. To a solution of free base tris(4-trifluoromethylphenyl)corrole (0.010 g, 0.014 mmol) in 2:1 dichloromethane/ethanol (15 mL) in a 50-mL round bottomed flask, was added sequentially $[Rh(cod)_2Cl]_2$ (0.0103g, 0.021 mmol, 1.5 equiv), NaOAc (0.017g, 0.21 mmol, 15 equiv), and triphenyl

phosphine (0.004g, 0.014 mmol, 1 equiv), and the mixture was stirred at room temperature for about 30-35 min while open to the atmosphere. Completion of the reaction was confirmed by UV-vis spectroscopy and mass spectrometry. The solvent was then removed by rotary evaporation, and the dark residue was chromatographed on a silica gel column with 9:1 n-hexane/CH₂Cl₂ as eluent. A dark red band that emerged second from the column was identified as containing Rh[TpCF₃PC](PPh₃). Recrystallization from hexane afforded the pure product (0.008 g, 0.007 mmol, 52%). UV–vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times$ $10^{-4} (M^{-1} cm^{-1})$]: 380 (sh) (1.93), 431 (4.45), 568 (1.39). ¹H NMR $(CDCl_3, 25 \ ^{\circ}C): \delta 8.78 \ (d, J = 4.3 \ Hz, 2H, \beta$ -pyrrolic), 8.59 $(d, J = 4.7 \ Hz)$ Hz, 2H, β -pyrrolic), 8.25 (d, J = 4.7 Hz, 2H, β -pyrrolic), 8.12 (d, J =4.3 Hz, 2H, β -pyrrolic), 8.11–7.86 (m, 11H, meso-aryl), 7.51 (d, I =7.8 Hz, 1H, meso-aryl), 7.08 (t, J = 7.3 Hz, 3H, p-H of PPh₃), 6.74-6.68 (m, 6H, m-H of PPh₃), 4.42 (dd, J = 12.4, 7.8 Hz, 6H, o-H of PPh₃). HRMS (major isotopomer) [M]⁺: 1092.1498 (exptl), 1092.1505 (calcd). Elemental analysis found (calcd): C, 63.57 (63.75); H, 3.75 (3.23); N, 5.04 (5.13).

Synthesis of Rh[TPC](PPh₃). Silica gel column chromatography with 9:1 *n*-hexane/ethyl acetate as eluent followed by recrystallization from 4:1 *n*-hexane/CH₂Cl₂ afforded the pure product (0.008 g, 0.009 mmol, 48%). UV–vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 381 (1.97), 429 (4.38), 566 (1.35). ¹H NMR (CDCl₃, 25 °C): δ 8.71 (d, *J* = 4.3 Hz, 2H, β -pyrrolic), 8.58 (d, *J* = 4.7 Hz, 2H, β -pyrrolic), 8.25 (d, *J* = 4.7 Hz, 2H, β -pyrrolic), 8.13 (d, *J* = 4.3 Hz, 2H, β -pyrrolic), 7.97 (br s, 5H, meso-aryl), 7.76–7.57 (m, 9H, meso-aryl), 7.47 (d, *J* = 6.9 Hz, 1H, meso-aryl), 7.04 (t, *J* = 7.6 Hz, 3H, *p*-H of PPh₃), 6.77–6.66 (m, 6H, *m*-H of PPh₃), 4.47 (dd, 6H, *J* = 12.3, 7.8 Hz, 6H, *o*-H of PPh₃). HRMS (major isotopomer) [M]⁺: 888.1866 (exptl), 888.1884 (calcd). Elemental analysis found (calcd): C, 73.71 (74.32); H, 4.53 (4.31); N, 6.33 (6.30).

X-ray quality crystals were obtained by slow evaporation of a concentrated solution of the complex in 3:1 n-hexane/CH₂Cl₂.

Synthesis of Rh[TpMePC](PPh₃). Silica gel column chromatography with 9:1 *n*-hexane/ethyl acetate as eluent followed by recrystallization from 4:1 *n*-hexane/CH₂Cl₂ afforded the pure product (0.009 g, 0.0097 mmol, 54%). UV–vis (CH₂Cl₂) λ_{max} [nm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 381 (1.84), 430 (3.99), 567 (1.23). ¹H NMR (CDCl₃, 25 °C): δ 8.68 (d, *J* = 4.3 Hz, 2H, β -pyrrolic), 8.58 (d, *J* = 4.7 Hz, 2H, β -pyrrolic), 8.25 (d, *J* = 4.7 Hz, 2H, β -pyrrolic), 8.13 (d, *J* = 4.3 Hz, 2H, β -pyrrolic), 7.92–7.80 (m, 5H, *meso*-aryl), 7.56–7.33 (m, 7H, *meso*-aryl), 7.02 (t, *J* = 7.4 Hz, 3H, *p*-H of PPh₃), 6.72–6.64 (m, 6H, *m*-H of PPh₃), 4.46 (dd, 6H, *J* = 12.2, 8.0 Hz, 6H, *o*-H of PPh₃), 2.65 (s, 6H, 5,15-Me), 2.62 (s, 3H, 10-Me). HRMS (major isotopomer) [M]⁺: 930.2374 (exptl), 930.2353 (calcd). Elemental analysis found (calcd): C, 73.73 (74.84); H, 5.49 (4.76); N, 5.50 (6.02).

Synthesis of Rh[TpOMePC](PPh₃). Silica gel column chromatography with *n*-hexane/ethyl acetate (4:1 decreasing to 1:1) as eluent followed by recrystallization from 3:1 *n*-hexane/CH₂Cl₂ afforded 0.0085g (0.0087 mmol) of pure Rh[TpOMePC](PPh₃). Yield = 54%. UV-vis (CH₂Cl₂) λ_{max} [mm, $\varepsilon \times 10^{-4}$ (M⁻¹ cm⁻¹)]: 380 (3.1), 427 (6.06), 567 (2.06). ¹H NMR (CDCl₃, 25 °C): δ 8.68 (d, J = 4.3 Hz, 2H, β -pyrrolic), 8.58 (d, J = 4.7 Hz, 2H, β -pyrrolic), 8.25 (d, J = 4.7 Hz, 2H, β -pyrrolic), 8.11 (d, J = 4.3 Hz, 2H, β -pyrrolic), 7.87 (broad-d, J = 8.0 Hz, 5H, meso-aryl), 7.35 (d, J = 8.1 Hz, 1H, meso-aryl), 7.29– 7.12 (m, 6H, meso-aryl), 7.02 (t, J = 7.2 Hz, 3H, p-H of PPh₃), 6.71– 6.64 (m, 6H, *m*-H of PPh₃), 4.45 (dd, J = 12.3 Hz, 7.8 Hz, 6H, *o*-H of PPh₃), 4.05 (s, 6H, 5,15-alkyl proton), 4.03 (s, 3H, 10-alkyl proton). HRMS (ESI⁺,major isotopomer): [M]⁺ = 978.2197 (expt.), 978.2201 (calcd.). Elemental analysis found (calcd): C 69.07 (71.17), H, 4.83 (4.53), N, 5.61 (5.72).

X-ray quality crystals were obtained by slow diffusion of n-heptane vapor into a concentrated benzene solution of the complex over 1 week.

Crystal Structure Determination. X-ray diffraction data were collected on beamline 11.3.1 at the Advanced Light Source. Single crystals were selected and coated in protective oil, before being transferred onto a MiTeGen kapton micromount and transferred to a Bruker D8 diffractometer fitted with a PHOTON100 CMOS detector operating in shutterless mode. The samples were cooled to 100(2) K

in a nitrogen stream provided by an Oxford Cryostream 800 Plus. Diffraction data were collected using a synchrotron with monochromated radiation using a silicon (111) crystal at $\lambda = 0.7749(1)$ Å. The structures were solved using dual space methods using SHELXT⁷⁶ and refined on F^2 using SHELXL-2014.⁷⁷ All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included at their geometrically estimated positions. One bromine atom in Co-[Br₈TpCF₃PC](PPh₃) was found to be disordered and was modeled over two sites with complementary occupancies. The two sites were constrained to have equal U_{ii} values.

Computational Methods. Ground state DFT calculations were carried with the ADF program system,⁷⁸ the B3LYP exchangecorrelation functional (20% Hartree-Fock exchange),^{79,80} and ZORA STO-TZP basis sets, both with and without the Grimme's D3 dispersion correction.⁸¹ DFT calculations related to the XAS/XES measurements were carried out with the ORCA 3.0.3 program using the BP86 optimized geometries followed by single-point spinunrestricted B3LYP calculations allowing for broken-symmetry solutions. For the latter calculations, we used the core properties basis sets as implemented in ORCA, viz. CP(PPP) for Co and the Ahlrichs's TZVP basis set for all other atoms. These calculations also employed the conductor-like screening model (COSMO) with a dielectric constant of 3.9 as well as appropriately fine grids and tight SCF convergence criteria. For TDDFT calculations of Co K pre-edge transitions, we set the number of roots at 40 and MaxDim at 400, selected "doQuad True," and did not calculate triplets. The TDDFT calculations were carried out over the entire valence manifold and for both spin-up (OrbWin = 0) and spin-down (OrbWin = 1) transitions. The calculated transition energies were broadened with half-widths of 1.7 eV to account for core-hole lifetime and instrument broadening and linearly upshifted by 164.5 eV for comparison with the experimental spectra.

X-Ray Absorption Data Collection and Analysis. The Co Kedge X-ray absorption spectra of Co[TPP], Co[TPP)(py)Cl, Co-[TPC](py)₂, and Co[TPC](PPh₃) were collected at the Stanford Synchrotron Radiation Lightsource under standard ring conditions of 3 GeV and ~500 mA on the unfocused 20-pole 2 T wiggler sidestation 7-3, equipped with a Si(220) double crystal monochromator for energy selection. The M₀ mirror was not employed, and the monochromator was detuned by \sim 55% to eliminate contributions from higher harmonics. All complexes were measured as solids ground to a homogeneous powder in a BN matrix. The sample was placed in Al spacers and wrapped in Kapton tape. During data collection, the samples were maintained at a constant temperature of ~10-15 K using an Oxford liquid He cryostat. Co K-edge EXAFS data were measured to k = 15 Å⁻¹ (transmission mode) using ion-chamber detectors. Internal energy calibration was accomplished by simultaneous measurement of the absorption of a Co-foil placed between the second and third ionization chambers situated after the sample. The data were calibrated to the first inflection point of the Co foil (7709.5 eV). Energy calibration, background correction, data averaging, and normalization were accomplished with ATHENA, which is part of the Demeter software package, version 0.9.24.82 The pre-edge region of the data sets was fit using Peak-Fit (SigmaPlot).

X-Ray Emission Data Collection and Analysis. Co K-edge XES spectra were measured on the 54-pole, 1-T wiggler beamline 6-2. A liquid-nitrogen-cooled double crystal Si(111) monochromator was used to set the incident energy at 9 keV. Vertical and horizontal focusing mirrors were used to achieve a beam size of 150×400 mm. Energy calibration was achieved with a Co foil. The first inflection point of the foil spectrum was set at 7709.5 eV. K β X-ray emission spectra were measured using the 533 reflection of five spherically bent Si crystal analyzers in combination with a silicon drift detector aligned in a Rowland geometry, as previously described.⁸³ The overall energy bandwidth of the X-ray emission spectrometer was ~1.5 eV. The data were normalized with respect to the K α line intensity. The K $\beta_{1,3}$ and the $K\beta_{valence}$ spectra were recorded separately using different regions with significant overlap between the two regions for accurate merging of the two data sets. A higher number of K β_{valence} scans was required to achieve similar signal quality.
