## Abstract

Unsupported and  $\text{Al}_2\text{O}_3$ -supported molybdenum phosphides (MoP) were tested as catalysts for the decomposition of hydrazine ( $\text{N}_2\text{H}_4$ ), in comparison with previously studied  $\text{Mo}_2\text{N}$  catalysts. The results showed that the activity increased with MoP loading on the MoP/ $\text{Al}_2\text{O}_3$  catalysts and that the supported MoP catalysts were more stable during hydrazine decomposition compared with the supported  $\text{Mo}_2\text{N}$  catalysts. FTIR results indicated that  $\text{N}_2\text{H}_4$  decomposed on the Mo sites on the MoP, similar to the case of  $\text{Mo}_2\text{N}$ . FTIR and microcalorimetric adsorption measurements showed that  $\text{NH}_3$  was adsorbed only moderately on the MoP catalyst, giving it better catalytic stability than the  $\text{Mo}_2\text{N}$ , for which strong adsorption of  $\text{NH}_3$  blocked the active sites and led to a sharp decrease in activity.

## 1. Introduction

The catalytic decomposition of  $\text{N}_2\text{H}_4$  is an important reaction used in microthrusters for satellite attitude control and maneuvering [1,2]. The conventional catalyst used in this reaction is Ir/ $\text{Al}_2\text{O}_3$ . However, due to its high price and relative scarcity, considerable research has been focused on the development of low-cost and widely available substitutes. It is known that transition metal nitrides and carbides catalyze many reactions that are typically catalyzed by noble metals [3–5]. Our previous work showed that  $\text{Al}_2\text{O}_3$ -supported  $\text{Mo}_2\text{C}$  and  $\text{Mo}_2\text{N}$ , with high mechanical strength, were as active as Ir/ $\text{Al}_2\text{O}_3$  for  $\text{N}_2\text{H}_4$  decomposition in a 10 N monopropellant thruster [6–9].

MoP is a metallic conductor with properties similar to intermetallic compounds. Some reports have been published concerning the use of MoP in hydroprocessing reactions [10–15]. Recently, we successfully synthesized a high-surface area MoP by combining citric acid with a temperature-programmed reduction (CA-TPR) method, and found that MoP also was active for  $\text{N}_2\text{H}_4$  decomposition [16]. In the present work, we studied

the catalytic performance and adsorption properties of the MoP in comparison with  $\text{Mo}_2\text{N}$ , with the aim of revealing the effect of metalloids on Mo atoms in  $\text{N}_2\text{H}_4$  decomposition.

## 2. Experimental

### 2.1. Catalyst preparation

Unsupported MoP was prepared according to the procedure of Stinner et al. [11]. Stoichiometric amounts of  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24}\cdot 4\text{H}_2\text{O}$  and  $(\text{NH}_4)_2\text{HPO}_4$  were dissolved in deionized water. After water evaporation, the white solid was further dried at 393 K for 12 h and calcined in air at 773 K for 5 h. The sample was then reduced with  $\text{H}_2$  at 923 K for 2 h, and finally passivated in a flow of 1%  $\text{O}_2/\text{N}_2$  for 2 h at room temperature.

MoP/ $\text{Al}_2\text{O}_3$  catalysts with loadings of 8, 13, and 20 wt% were synthesized by impregnating  $\gamma\text{-Al}_2\text{O}_3$  support with an aqueous solution of  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24}\cdot 4\text{H}_2\text{O}$  and  $(\text{NH}_4)_2\text{HPO}_4$ . To obtain 20 wt% MoP loading, double impregnations were used. After drying and calcining, the samples were reduced at 1123 K for 2 h and then passivated in a flow of 1%  $\text{O}_2/\text{N}_2$  for 2 h at room temperature.

Unsupported  $\text{Mo}_2\text{N}$  and supported  $\text{Mo}_2\text{N}/\text{Al}_2\text{O}_3$  were prepared by the temperature-programmed reaction of  $\text{MoO}_3$  and  $\text{MoO}_3/\text{Al}_2\text{O}_3$  (8.7 wt%) with  $\text{NH}_3$  [8].

## 2.2. Catalyst tests

Catalytic tests were performed at atmospheric pressure in a microreactor [8]. A catalyst sample (40 mg for unsupported catalysts and 50 mg for supported catalysts) was diluted with silica and placed in the quartz reactor. Before the reaction, the catalyst was prereduced in  $\text{H}_2$  at 923 K (for MoP) or 973 K (for  $\text{MoP}/\text{Al}_2\text{O}_3$ ) for 0.5 h. Similarly, the unsupported  $\text{Mo}_2\text{N}$  and  $\text{Mo}_2\text{N}/\text{Al}_2\text{O}_3$  were renitrided with  $\text{NH}_3$  at 973 K for 0.5 h before the activity tests. The feed gas  $\text{N}_2\text{H}_4/\text{Ar}$  (3% V/V) was introduced into the reactor at a rate of  $85 \text{ ml min}^{-1}$ .  $\text{N}_2\text{H}_4$  conversion and  $\text{H}_2$  selectivity were used to evaluate the catalytic performance [17].

## 2.3. $\text{NH}_3$ microcalorimetry

The microcalorimetry of  $\text{NH}_3$  adsorption was performed at 423 K using a Calvet-type microcalorimeter (Setaram BT 2.15) [18]. Before measurements, the samples were pretreated following the same procedures used for reaction tests. The samples were outgassed at the final temperature for 0.5 h, and then cooled to room temperature to allow sample transference. The microcalorimetric data were collected by successively introducing doses of  $\text{NH}_3$  to the sample. The dead volume of the volumetric apparatus was carefully calibrated by He expansion.

## 2.4. FTIR studies

FTIR spectra were collected at room temperature with a Bruker Equinox 55 spectrometer at a resolution of  $4 \text{ cm}^{-1}$  using 64 scans. Before adsorption, the samples were pretreated following the same procedures used for the reaction tests, then cooled to room temperature and evacuated to about  $10^{-3} \text{ Pa}$ . The probing gases, including  $\text{N}_2\text{H}_4$ ,  $\text{CO}$ , and  $\text{NH}_3$ , were purified with liquid nitrogen.  $\text{N}_2\text{H}_4$  was dosed from a variable leak valve.

## 3. Results and discussion

### 3.1. Reactivity studies

Fig. 1 shows the  $\text{N}_2\text{H}_4$  conversions at 303 K with time on stream over the various MoP and  $\text{Mo}_2\text{N}$  catalysts. The conversion of  $\text{N}_2\text{H}_4$  over the unsupported MoP was  $>90\%$  initially and gradually decreased with time on stream, to 85% after a 170-min run. It was 100% on the unsupported  $\text{Mo}_2\text{N}$  in the initial 20 min, but rapidly decreased to  $<80\%$  after 170 min on stream. For the supported MoP catalysts,  $\text{N}_2\text{H}_4$  conversion was enhanced with increased MoP loading and remained stable during the reaction period. For the  $\text{Al}_2\text{O}_3$ -supported  $\text{Mo}_2\text{N}$  catalyst, rapid deactivation behavior was observed during an 80-min run, indicating the supported  $\text{Mo}_2\text{N}$  catalysts have better stability than the supported  $\text{Mo}_2\text{N}$  in  $\text{N}_2\text{H}_4$  decomposition reaction.

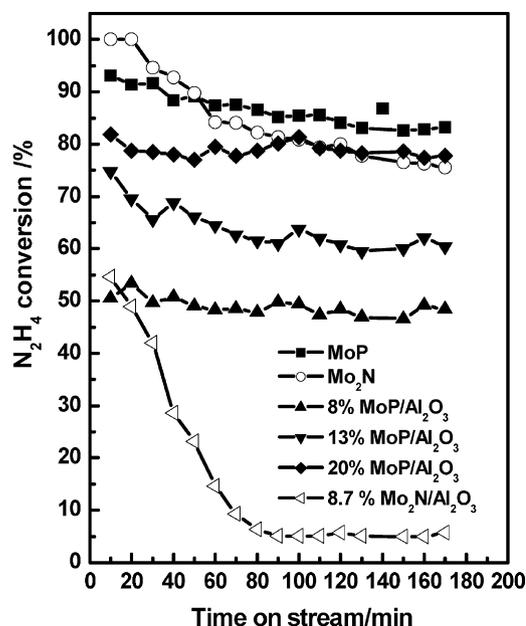

Fig. 1.  $\text{N}_2\text{H}_4$  conversions at 303 K with the time on stream over supported and unsupported MoP and  $\text{Mo}_2\text{N}$  catalysts.

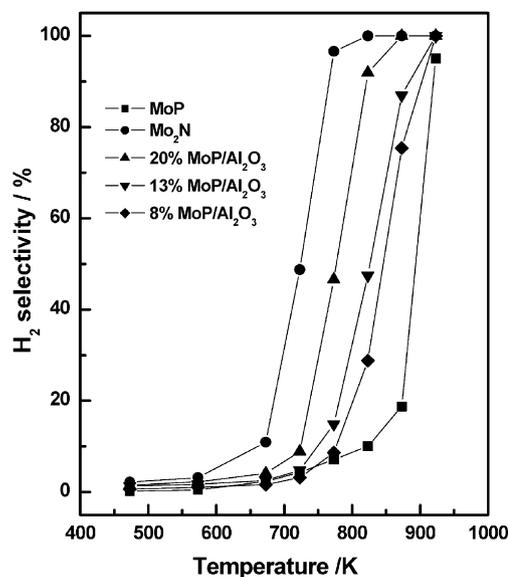

Fig. 2. Variation in  $\text{H}_2$  selectivities with the reaction temperature over MoP,  $\text{Mo}_2\text{N}$ , and  $\text{MoP}/\text{Al}_2\text{O}_3$  catalysts.

Fig. 2 presents the  $\text{H}_2$  selectivities with the reaction temperature over the different catalysts. The selectivities on all catalysts were low below 673 K. With increasing the reaction temperature, the generated  $\text{NH}_3$  could be further dissociated, leading to the production of  $\text{H}_2$  [8,9,17]. The unsupported  $\text{Mo}_2\text{N}$  exhibited the highest  $\text{H}_2$  selectivities among all the investigated samples, suggesting that  $\text{Mo}_2\text{N}$  is a good catalyst for  $\text{NH}_3$  decomposition [3]. In contrast to  $\text{Mo}_2\text{N}$ , the unsupported MoP shows the lowest  $\text{H}_2$  selectivity, indicating that it is a poor catalyst for  $\text{NH}_3$  decomposition.  $\text{H}_2$  selectivity was improved when supporting MoP onto  $\text{Al}_2\text{O}_3$ , and also increased with increasing MoP loading.

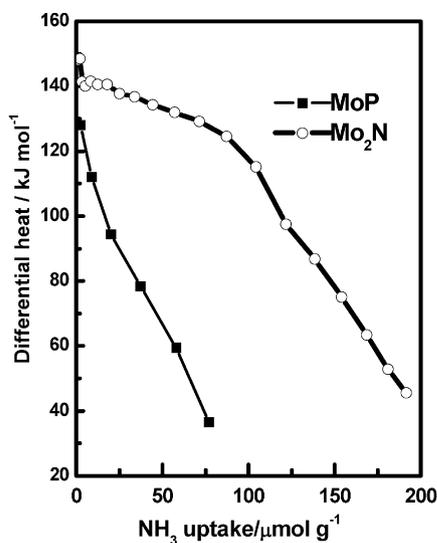

Fig. 3. Differential heats of NH<sub>3</sub> adsorption versus uptake on MoP and Mo<sub>2</sub>N at 423 K.

### 3.2. NH<sub>3</sub> adsorption microcalorimetry

Because NH<sub>3</sub> is both a product and intermediate in hydrazine decomposition [2], it can be used as a probe to study the active sites of MoP or Mo<sub>2</sub>N catalysts. Fig. 3 shows the differential heats versus the NH<sub>3</sub> adsorption uptake for MoP and Mo<sub>2</sub>N at 423 K. For MoP, the heat of NH<sub>3</sub> adsorption was 130 kJ mol<sup>-1</sup> initially and dropped dramatically to the range of physical adsorption (<40 kJ mol<sup>-1</sup>). The trend of continuously decreasing differential heat indicates a highly heterogeneous surface of the MoP. The initial adsorption heat of NH<sub>3</sub> on Mo<sub>2</sub>N was as high as 148 kJ mol<sup>-1</sup>, and the differential heat curve showed a plateau above 130 kJ mol<sup>-1</sup>. The adsorption heat then decreased gradually to 40 kJ mol<sup>-1</sup>. These findings indicate that the NH<sub>3</sub> adsorption is much stronger on Mo<sub>2</sub>N than on MoP.

The differences in NH<sub>3</sub> adsorption on MoP and Mo<sub>2</sub>N shown in the microcalorimetric experiments could be due to the difference in surface sites. A 3*p*-group element should not be as strong as a 2*p*-group element as an electron acceptor. A theoretical study based on density functional theory (DFT) has shown that the Mo–P bond in MoP is less ionic than the Mo–N bond in Mo<sub>2</sub>N [14]. Thus, the Mo in Mo<sub>2</sub>N should have stronger Lewis acidity than the Mo in MoP, resulting in stronger adsorption of NH<sub>3</sub> on Mo<sub>2</sub>N. For the decomposition of N<sub>2</sub>H<sub>4</sub>, such strongly bound NH<sub>3</sub> and/or nitrogen fragments left on the catalyst surface may poison the catalyst, possibly accounting for the declining activity of Mo<sub>2</sub>N. The relatively weak NH<sub>3</sub> adsorption on MoP might be the reason for its low H<sub>2</sub> selectivity in the decomposition of N<sub>2</sub>H<sub>4</sub>.

### 3.3. FTIR

To gain insight into the nature of the N<sub>2</sub>H<sub>4</sub> decomposition on the MoP catalysts and shed light on the difference between MoP and Mo<sub>2</sub>N catalysts, FTIR studies were carried out with CO as a probe molecule and N<sub>2</sub>H<sub>4</sub> as a reactant molecule.

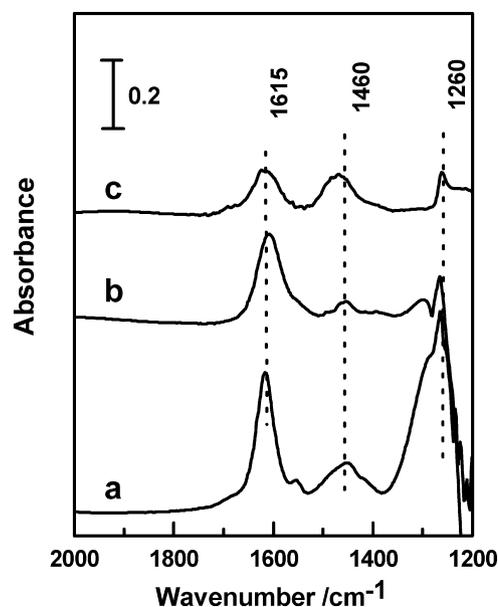

Fig. 4. IR spectra of (a) NH<sub>3</sub> adsorption on MoP/Al<sub>2</sub>O<sub>3</sub>; N<sub>2</sub>H<sub>4</sub> adsorption on (b) MoP/Al<sub>2</sub>O<sub>3</sub> and (c) Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> at room temperature.

#### 3.3.1. NH<sub>3</sub> and N<sub>2</sub>H<sub>4</sub> adsorption

Fig. 4 shows the IR spectra of adsorbed NH<sub>3</sub> on MoP/Al<sub>2</sub>O<sub>3</sub> and adsorbed N<sub>2</sub>H<sub>4</sub> on MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> catalysts at room temperature. Adsorbed NH<sub>3</sub> on MoP/Al<sub>2</sub>O<sub>3</sub> yielded IR bands at 1615, 1460, and 1260 cm<sup>-1</sup>, corresponding to the characteristic frequencies of NH, NH<sub>4</sub><sup>+</sup>, and molecularly adsorbed NH<sub>3</sub> [19]. Similar results were obtained when N<sub>2</sub>H<sub>4</sub> was adsorbed on MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>, suggesting that the decomposition of N<sub>2</sub>H<sub>4</sub> occurred at room temperature and produced NH<sub>3</sub>.

#### 3.3.2. CO and N<sub>2</sub>H<sub>4</sub> coadsorption

Fig. 5 shows the IR results for the co-adsorption of N<sub>2</sub>H<sub>4</sub> and CO on MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>. CO adsorption alone on MoP/Al<sub>2</sub>O<sub>3</sub> gave an IR band at 2048 cm<sup>-1</sup> (Fig. 5a); this can be attributed to linearly adsorbed CO on the Mo atoms [20,21]. Adsorption of N<sub>2</sub>H<sub>4</sub> onto CO-preadsorbed MoP/Al<sub>2</sub>O<sub>3</sub> produced three bands at 1615, 1460, and 1260 cm<sup>-1</sup> due to adsorbed NH<sub>3</sub>, accompanied by a red shift of ν<sub>CO</sub> from 2048 to 1960 cm<sup>-1</sup>. This suggests that the decomposition of N<sub>2</sub>H<sub>4</sub> occurred on the Mo sites of the MoP. On the other hand, CO adsorption alone on Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> yielded an IR band at around 2200 cm<sup>-1</sup> in addition to the band at 2048 cm<sup>-1</sup>. The band at 2200 cm<sup>-1</sup> can be assigned to the CO adsorbed on the surface N sites of Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> [20]. When N<sub>2</sub>H<sub>4</sub> was adsorbed on the CO-preadsorbed Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>, the aforementioned three bands due to NH<sub>3</sub> adsorption were present, the band at 2048 cm<sup>-1</sup> disappeared, and the band at 2200 cm<sup>-1</sup> shifted slightly to 2185 cm<sup>-1</sup>. This finding again indicates that N<sub>2</sub>H<sub>4</sub> decomposed on the Mo sites of the Mo<sub>2</sub>N, and the NH<sub>3</sub> adsorption on the Mo sites of the Mo<sub>2</sub>N was so strong so as to push away the preadsorbed CO on those sites.

Fig. 5B shows the IR results for adsorbed CO on N<sub>2</sub>H<sub>4</sub>-preadsorbed MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>. The band at 1970 cm<sup>-1</sup> assigned to adsorbed CO was evident on the MoP/

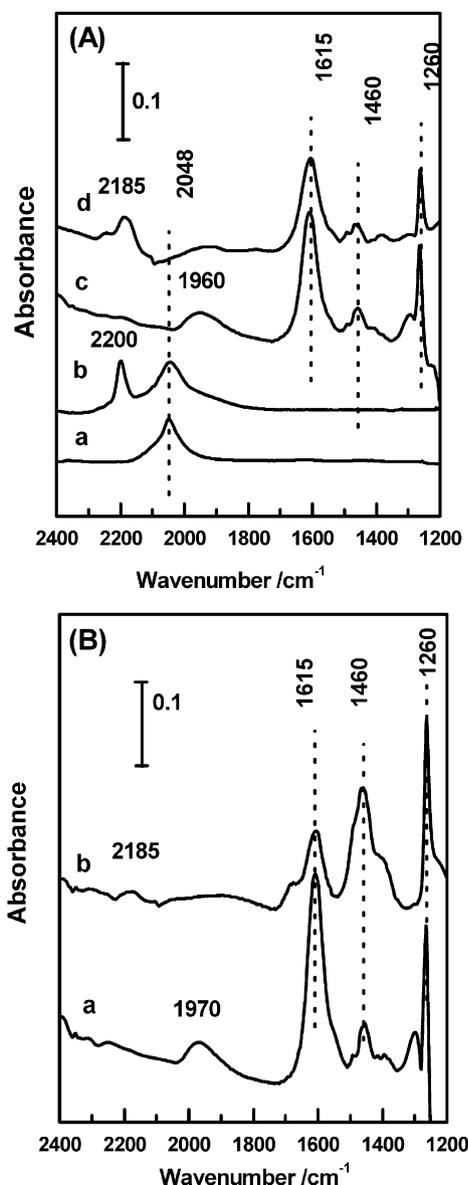

Fig. 5. (A) IR spectra of (a, b) CO adsorption on MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>; (c, d) N<sub>2</sub>H<sub>4</sub> adsorption on CO-pretreated MoP/Al<sub>2</sub>O<sub>3</sub> and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>; (B) IR spectra of CO adsorption on N<sub>2</sub>H<sub>4</sub>-pretreated MoP/Al<sub>2</sub>O<sub>3</sub> (a) and Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> (b).

Al<sub>2</sub>O<sub>3</sub>, whereas it was no longer observed on the Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>. This finding again confirms that hydrazine decomposition occurred on the Mo sites and that CO and N<sub>2</sub>H<sub>4</sub> were competing for the same Mo sites on the catalysts. Due to the stronger adsorption of NH<sub>3</sub> on the Mo sites of the Mo<sub>2</sub>N compared with those of the MoP, CO could not be adsorbed on those N<sub>2</sub>H<sub>4</sub>-pretreated sites of the Mo<sub>2</sub>N catalyst.

Consistent with the results of microcalorimetric NH<sub>3</sub> adsorption, FTIR offered more evidence showing that NH<sub>3</sub> was more readily adsorbed on Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> than on MoP/Al<sub>2</sub>O<sub>3</sub>. Thus, the NH<sub>3</sub> and/or the nitrogen fragments were not easily desorbed from the Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub> surface and may have blocked

the active sites, leading to decreased activity during N<sub>2</sub>H<sub>4</sub> decomposition.

#### 4. Conclusion

This study found that both supported and unsupported MoP were active and stable for the decomposition of N<sub>2</sub>H<sub>4</sub> at room temperature, but less active for the decomposition of NH<sub>3</sub>. N<sub>2</sub>H<sub>4</sub> adsorbed and decomposed on the Mo sites for both MoP and Mo<sub>2</sub>N, but the metalloid elements in MoP and Mo<sub>2</sub>N had a significant effect on the N<sub>2</sub>H<sub>4</sub>-derived NH<sub>3</sub> adsorption. MoP/Al<sub>2</sub>O<sub>3</sub> exhibited relatively weaker adsorption for NH<sub>3</sub> than Mo<sub>2</sub>N/Al<sub>2</sub>O<sub>3</sub>. As a result, in the decomposition of N<sub>2</sub>H<sub>4</sub>, the strongly bound nitrogen adspecies on Mo<sub>2</sub>N accumulated, and the intermediates on MoP were readily desorbed from the active sites, leading to a relatively better stability of MoP. The moderate adsorption of NH<sub>3</sub> might also be the reason for the poor H<sub>2</sub> selectivity for the N<sub>2</sub>H<sub>4</sub> decomposition over the MoP at high temperatures.
