

An Improved Synthesis of $\alpha,\alpha,\alpha',\alpha'$ -Tetramethyldicarboxylic Acids

GEORGE R. NEWKOME, et. al.,¹

Department of Chemistry, Louisiana State University, Baton Rouge, Louisiana, U.S.A.

The synthesis of $\alpha,\alpha,\alpha',\alpha'$ -tetramethyldicarboxylic acids (**1**), via the classical method of Haller and Bauer² from isobutyrophenone (**2**) through intermediates **3** and **4**, has been described by Adams and Anderson³ as well as others⁴. This synthetic procedure has numerous major disadvantages:

- three time consuming separate steps,
- an extremely difficult hydrolysis of diamide **4**, resulting in easily contaminated diacid **1**,
- decomposition of the initial diketone **3** upon attempted purification,
- moderately expensive starting material **2**, or, if unavailable, an additional step from 2-methylpropanoic acid (**5**).

We have found that these tetrasubstituted dicarboxylic acids can be conveniently prepared in a single flask by alkylation of the α -anion of 2-methylpropanoic acid (**6**)⁵, which is

formed by the reaction of lithium diisopropylamide and **5** in the tetrahydrofuran. Hexamethylphosphoric triamide is used as a cosolvent; however, comparable yields can be realized without hexamethylphosphoric triamide. The yield data of the purified diacids are given in the Table and reflect a *minimum* value.

It was previously observed³ that the melting points of unsubstituted dicarboxylic acids approach each other with increasing carbon chains. This phenomenon was not observed in the series of substituted diacids³; however, this original observation was based upon impure diacid products.

When pure diacids are used, there seems to be an approachment in melting point data but approximately 30° lower than that reported³ for the corresponding unsubstituted diacids.

Table. Preparation of $\alpha,\alpha,\alpha',\alpha'$ -Tetramethyldicarboxylic Acids (**1**)

n	Yield (%) ^{a,b}	M.p. ^b
3	42, 52° (26, Lit. ⁴ 46)	168–170 ^{od} (168–169°)
4	39 (47, Lit. ⁴ 41)	185–187 ^{od} (179–181°) (Lit. ⁴ 185.8–186.1°)
5	62 (50)	140–141 ^{od} (139.5–141°)
6	46, 40° (46)	118–121 ^{od} (117–118°)
7	53 (28)	76–77 ^{oc} (75–77°)
8	48 (22)	92–93 ^{oc} (86–88°)
9	68 (11)	73–74 ^{of} (57–59°)
10	52 (47)	87.5–89 ^{of} (84–86°)

^a Isolated, recrystallized products; reaction yields were not optimized.

^b Value in brackets is that reported in reference 3.

^c Without hexamethylphosphoric triamide cosolvent.

^d Recrystallized from ethyl acetate.

^e Recrystallized from petroleum ether (b.p. 60–80°).

^f Recrystallized from petroleum ether (b.p. 40–60°).

Preparation of $\alpha,\alpha,\alpha',\alpha'$ -Tetramethylheptanedioic Acid (**1**; n=3):

General Procedure:

To a mixture of tetrahydrofuran (130 ml) and redistilled diisopropylamine (19.6 g, 0.196 mol) cooled to –20° was added via a hypodermic syringe 2.1 M *n*-butyllithium (11.0 g, 0.196 mol) in hexane while maintaining the temperature below 0° under nitrogen. After 30 minutes, 2-methylpropanoic acid (7.75 g, 0.088

mol) was added dropwise still maintaining the temperature at -20° , then hexamethylphosphoric triamide (17.9 g, 0.10 mol) was added. The mixture was allowed to warm slowly to 50° and this temperature was maintained for 2 hours. The pale yellow solution was cooled to -20° , and 1,5-dibromopentane (10.12 g, 0.044 mol) was added at a rate to keep the temperature below 0° . The reaction mixture was heated to 40° for 1 hour, then hydrolyzed by ice-cold 10% hydrochloric acid (300 ml). The resultant solution (with possible suspension) was extracted with dichloromethane (3×100 ml). The combined organic layers were washed with 10% hydrochloric acid (4×10 ml), then water (2×100 ml), dried over anhydrous magnesium sulfate, and concentrated *in vacuo* to afford a pale yellow oil, from which white crystals precipitated. Recrystallization of the crude product from petroleum ether (b.p. $60-80^{\circ}$) gave $\alpha,\alpha,\alpha',\alpha'$ -tetramethylheptanedioic acid; yield: 13.3 g (62%); m.p. $140-141^{\circ}$; lit.³ m.p. $139.5-141^{\circ}$.
