

At present, we are not aware of any evidence in solvolyses of simple secondary substrates that requires postulating hidden return of large magnitude.<sup>35-37</sup> All kinetic data for nonanchimerically assisted substrates can be quantitatively explained, within a small rate factor, by varying degrees of nucleophilic solvent assistance. Such nucleophilic assistance is reduced in weakly nucleophilic solvents and sterically hindered substrates;<sup>38</sup> in these situations, the carbonium ion character of the transition state is greater and inductive/hyperconjugative effects are larger in magnitude.<sup>12,16</sup>

## Selective Steroid Halogenations Directed by Proximity and Substituent Effects

Sir:

We have reported<sup>1</sup> that certain free radical halogenating reagents, and in particular phenyliodine dichloride, are sufficiently selective that in a random attack on a steroid nucleus halogenation occurs to an appreciable extent only at carbons 5, 9, and 14. Furthermore, our previous work indicated that the proportion of attack among these three positions could be influenced by substituents on the steroid skeleton. Halogenation at C-9 allows easy introduction of the 9(11) double bond which permits entry into the corticosteroids; our procedure has also been utilized by Djerassi<sup>2</sup> in the synthesis of a starfish sterol. Halogenation at C-14, and subsequent introduction of the  $\Delta$ 14 double bond in a steroid, is of interest with respect to the synthesis of cardiac active steroids.

Although in the previously described procedure appropriate substituents could suppress attack at C-5 and allow the production of various proportions of  $\Delta$ 9(11) and  $\Delta$ 14 steroids, it would clearly be desirable to be able to direct exclusively the introduction of one or the other of these functionalities. We now wish to

report that with appropriate substituent effects we can direct the halogenation to the introduction of a 9(11) double bond in an attractive corticosteroid precursor.<sup>3</sup> Alternatively, by the application of intramolecular orientation procedures to this halogenation, we have been able to direct it to the selective introduction of the  $\Delta$ 14 double bond or the 9(11) double bond.

Although bulky substituents at C-17 have some effect in suppressing the halogenation at C-14, the most convenient and effective group is simply the C-17 carbonyl, which deactivates C-14 to halogenation presumably by a combination of polar and conformational effects. As we have indicated earlier, C-5 halogenation can be diminished by attachment of an electron-withdrawing group at C-3, and particularly effective is a  $3\alpha$  substituent which is thus 1,3-diaxial with the C-5 hydrogen. Commercially available androsterone was converted to its trifluoroacetate (I), mp 123.5–124°, <sup>4</sup>

and 1.0 g was halogenated with 1 equiv of  $C_6H_5ICl_2$  in benzene at  $10^{-2}$  M by irradiation with a sun lamp for 10–15 min. The product was then dehydrochlorinated and saponified with methanolic KOH, acetylated, and chromatographed. Unfunctionalized androsterone acetate (25%) was separated from  $3\alpha$ -acetoxy- $5\alpha$ -androst-9(11)-en-17-one (II), mp 187.5–189°, <sup>4</sup> (41%) and ca. 5% of the corresponding  $\Delta$ 5 isomer. The remaining 25% of more polar material, containing chlorine, was formed by further halogenation.<sup>5</sup> With 2 equiv of  $C_6H_5ICl_2$  conversion was 95%, with 49% of II being isolated. Again the only other products detected are a trace of the  $\Delta$ 5 isomer, and 34% of polar products of further reaction.

Selective functionalization at C-14 was obtained by applying our principle of remote oxidation to this halogenation process. We have described selective functionalization of steroids by attached benzophenone<sup>6,7</sup> or nitrite ester derivatives,<sup>7</sup> but it was problematical whether internal attack by a rigid attached reagent far from the attachment point could also be applied in a radical chain reaction. In a chain process there must be both an intramolecular hydrogen transfer in the attack on the substrate and an intermolecular halogen transfer to carry the chain. For the former, low concentrations are required to suppress competing intermolecular hydrogen abstractions, and under these conditions it is not necessarily clear that the chain transfer steps would be possible. However, it turns out that halogenation by  $C_6H_5ICl_2$  can indeed be turned into a

(3) Introduction of the appropriate side chain, conversion of a  $\Delta$ 9(11) double bond to an 11-oxy substituent, and modification of ring A to a  $\Delta$ 4-3-one system are all well-known processes.

(4) Characterized by mass and pmr spectra.

(5) Apparently some of the olefin is formed directly and reacts further during halogenation. Treatment of II with  $C_6H_5ICl_2$  in the dark, followed by our standard work-up, afforded similar polar material.

predominantly intramolecular remote functionalization. The *p*-iodophenylacetic ester,<sup>8</sup> mp 95–97°, of 3 $\alpha$ -cholestanol was converted with Cl<sub>2</sub> to the corresponding dichloride III. Irradiation of a  $0.33 \times 10^{-3}$  M solution

of ester III in chlorobenzene at  $-25^\circ$  with a sun lamp, followed by hydrolysis and work-up as above, yielded 20% of recovered cholestanol (acetate) and 53% of  $\Delta 14$ -cholestenyl 3 $\alpha$ -acetate (IV) identical with authentic material.<sup>6</sup> In addition only 5% of the  $\Delta 9(11)$  isomer and 0.8% of the  $\Delta 5$  isomer were detected, along with polar and unidentifiable material. These other isomers must have been formed in a competing intermolecular process, since  $0.33 \times 10^{-3}$  M androstane included in the reaction mixture as a control was converted to 9% of the expected mixture of androstenes. The intramolecular process is apparently completely selective for C-14; more intermolecular, randomized, halogenation is seen at room temperature or with higher concentrations.

Remote oxidation by benzophenone esters attached to 3 $\alpha$  occurs at C-14 with some para derivatives but in ring B with the corresponding meta esters.<sup>7</sup> This proves to be true for attached PhICl<sub>2</sub> as well. Thus 3 $\alpha$ -cholestanyl *m*-iodobenzoate,<sup>8</sup> mp 89.5–90.5°, was converted to the dichloride V and irradiated in benzene at

$1.0 \times 10^{-3}$  M and room temperature. After hydrolysis, etc., 35% of 3 $\alpha$ -cholestanol (acetate) was recovered, and 43% of  $\Delta 9(11)$ -cholestenyl 3 $\alpha$ -acetate (VI) was isolated, mp 80.5–82°, which was hydrolyzed to the known<sup>6</sup>  $\Delta 9(11)$ -3 $\alpha$ -cholestanol. Only 9% of the  $\Delta 14$  isomer was formed and 2% of the  $\Delta 5$  olefin. In a control reaction, androstane at  $1.0 \times 10^{-3}$  M was 20% functionalized, so the intermolecular process has not been completely suppressed. The yield of VI and conversion of V are even higher for reaction in CH<sub>2</sub>Cl<sub>2</sub>.

The selective attack at C-14 in III, and C-9 in V, is consistent with predictions from molecular models

assuming that hydrogen abstraction is done by the chlorine atom in the [Ar–I–Cl]· intermediate.<sup>9</sup> The chlorine atom in the intermediate derived from III is in fact in essentially the same place as is the abstracting oxygen in the *p*-benzophenoneacetic ester of 3 $\alpha$ -cholestanol, whose photolysis also produced a  $\Delta 14$ -3 $\alpha$ -cholestanol derivative.<sup>6</sup> The present work not only furnishes alternative and convenient approaches to this olefin and to the important  $\Delta 9(11)$  unsaturation but it also demonstrates that the principles we have developed in connection with intramolecular benzophenone photochemistry can be extended to impose orientation factors on radical chain processes.<sup>10</sup>

(9) D. D. Tanner and P. B. van Bostelen, *J. Org. Chem.*, **32**, 1517 (1967), suggest abstraction by iodine to form an unstable trivalent iodine derivative which then loses HCl. Such a mechanism looks energetically unfavorable and is not geometrically possible for III.

### Stereochemistry of the Di- $\pi$ -methane Rearrangement at the Methane Carbon. Mechanistic and Exploratory Organic Photochemistry<sup>1</sup>

Sir:

In our earlier studies on the di- $\pi$ -methane rearrangement,<sup>1–4</sup> we found that retention of configuration is the preferred stereochemistry at carbons 1 and 5 of the 1,4-pentadiene system. We did encounter some evidence in constrained systems<sup>5</sup> pointing toward a preference for inversion of configuration at the one other stereochemical center, namely the methane carbon (*i.e.*, C-3). Mariano in his elegant studies has attacked the problem from another perspective and demonstrated that in constrained di- $\pi$ -methane systems it is possible to enforce either retention or inversion of configuration.<sup>6</sup>

The present research aimed at determination of the preferred C-3 stereochemistry in an unconstrained, acyclic system. For this we selected 3-ethyl-3,5-dimethyl-1,1-diphenyl-1,4-hexadiene (1). It was found that the di- $\pi$ -methane rearrangement of ethylmethyl-1,4-hexadiene 1 led to *cis*- and *trans*-3-ethyl-3-methyl-2-(2'-methylpropenyl)-1,1-diphenylcyclopropane (2a and b) with a quantum yield of 0.11. Optically active ethylmethyl-1,4-hexadiene 1 was prepared as were optically active *cis*- and *trans*-vinylcyclopropanes 2a and 2b.<sup>7</sup> The con-
