threonine, L-tryptophan, L-tyrosine, and L-valine. At 1 mg/5 ml, almost all of these substances caused a toxicity reversal. An investigation was thus carried out at 100 μ g/5 ml to determine which substances at lower concentrations would reverse the toxicity. It was found that isoleucine, leucine, and valine were much more powerful reversal agents than the others and were examined further. Table I shows the results where tenfold concentration differences in these particular compounds were employed.

Work with Mice.—The comparative toxicity of the substances in Robidoux albino male mice (20 g) was examined in the following manner. Each of the four compounds was injected at 500 mg/kg; 0.2 ml of a saline solution of the compound at pH 7 was injected intraperitoneally in an aseptic manner once daily for 6 consecutive days; a minimum of six mice were employed for each compound. The animals were then allowed to rest for 8 days, following which they were sacrificed and a brief autopsy was performed. Figure 1 shows the results of the weight changes observed.

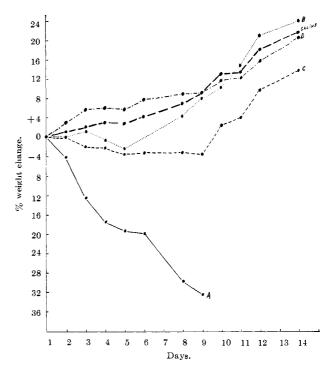

Figure 1.—Weight changes in mice following injections of compounds indicated: A = ACPC, B = compound II, C = compound III, and D = compound I.

Some Arylalkylamino Analogs of Acyclic Analgetics

A. F. Casy and M. M. A. Hassan

Faculty of Pharmacy, University of Alberta, Edmonton, Alberta

Received January 19, 1968

Replacement of N-methyl by N-phenethyl in analgetics where the nitrogen atom forms part of an alicyclic system (e.g., morphine, and morphinan, benzomorphan, and 4-phenylpiperidine derivatives) invariably produces a compound of enhanced potency.¹ Data pertaining to the same structural modification in acyclic analgetics are sparse, however, the basic

600

anilide **1a** (diampromid),² its thienyl analogs,³ and 2-ethoxy-N-methyl-N-[2-(methylphenethylamino)ethyl]-2,2-diphenylacetamide⁴ being the only examples of open-chain analgetics containing the N-phenethyl function. For this reason, and as part of a comparative study of structure-activity relationships in 3-amino-1,1-diphenylpropylamine and N-(2-aminopropyl)propionanilide analgetics,⁵ the synthesis of the Nphenethyl analogs of methadone and isomethadone was undertaken.

The standard procedure of alkylating diphenylacetonitrile with the appropriate 1-amino-2-chloropropane⁶ gave a 1:1.5 mixture of the precursor nitriles (2a and 3a) formed through the ethyleniminium ion intermediate 4. Pmr characteristics of the two

Janssen, "Synthetic Analgesics," Part 1, Diphenylpropylamines, Pergamon Press, Oxford, 1960, p 122. basis of its lower field *sec*-methyl and N-methyl signals (the relative chemical shifts of *sec*-methyl in 2- and 3-methyl derivatives reflects the greater proximity of 2-methyl to the deshielding cyano substituent).⁷ The differing stabilities of the ketimines **2b** and **3b** formed by treating the nitriles with ethylmagnesium bromide (that from the major isomer required more drastic hydrolysis conditions) confirmed these structural assignments.⁸

The phenethylamino analogs of methadone (2c) and isomethadone (3c) were both devoid of activity when tested in mice by the hot-plate assay at dose levels of greater than 40 mg/kg (subcutaneous route),⁹ results showing them to possess no significant analysic properties. In comparison, hot-plate ED₅₀ values for methadone and isomethadone in mice (measured in the same laboratory) are 5.2 and 7.9 mg/kg, respectively.¹⁰ The relative analgetic activities of N-dimethyl and derivatives of 6-amino-4,4-N-methylphenethyl diphenvlheptan-3-one are thus in sharp contrast with those of diampromid (1a) and its dimethylamino congener (1b) since, in the latter pair, the arylalkylamino member is by far the more potent compound.^{2,5} These results substantiate the view, already advanced on the basis of differing stereospecificities and properties of N-benzylmethylamino analogs,^{5,11} that 3amino-1,1-diphenylpropyl and basic anilide analgetics differ in their modes of binding to the analystic receptor.

A basic function containing an aryl group is a necessary feature for activity in diampromid and related analgetics, and it was thus of interest to examine the dibenzylamino analog 1c in which two additional aromatic groups are potentially available for binding. This compound was prepared unambiguously from 2-bromopropionyl bromide by adapting the procedure of Wright, *et al.*² ($5 \rightarrow 7 \rightarrow 1c$) (Scheme I), and was also

obtained by alkylating propionanilide with 2-chloro-1dibenzylaminopropane. In the alkylation reaction, steric factors must govern opening of the ethyleniminium ion **4** since the anilide **1c**, obtained by nucleophilic attack at the less hindered C-1 position, was the exclusive product.

The dibenzylaminoanilide **1c** proved to be inactive at dose levels greater than 40 mg/kg (hot-plate test in mice)¹⁰ and possible reasons for the adverse effect of the additional phenyl group upon activity are its steric bulk (impeding binding to the receptor) and baseweakening influence (reducing the proportion of protonated species). The dibenzylamino anilide (p $K_a' =$ 5.66) is significantly weaker a base than the an-

algetically active benzylmethylamino congener 1 [R = $N(CH_3)CH_2C_6H_5$], $pK_{a'} = 7.16$ in 50% ethanol.

Experimental Section¹²

1-Methylphenethylamino-2-chloropropane.—Redistilled SOCl₂ (125 ml) in CHCl₃ (125 ml) was added to 1-methylphenethylamino-2-propanol¹⁸ (99 g) in CHCl₃ (200 ml); the mixture was heated under reflux for 5 hr and then evaporated. The residue solidified after trituration with ether and was recrystallized from EtOH-Et₂O to give the chloroamine hydrochloride (102 g), mp 121-123°. Anal. (Cl₂H₁₉Cl₂N) C, H, N. The derived base has bp 148° (20 mm). Anal. (Cl₂H₁₉ClN)

The derived base has bp 148° (20 mm). Anal. ($C_{12}H_{18}CIN$) C, H, N, equiv wt.

It formed a picrate, mp 111–113° from EtOH. Anal. ($C_{18}H_{21}$ -ClN₄O₇) C, H.

2- and 3-Methyl-3-methylphenethylamino-1,1-diphenylpropyl Cyanides (3a and 2a).—1-Methylphenethylamino-2-chloropropane (44.3 g) was added to a mixture of diphenylacetonitrile (42.5 g), C_6H_6 (120 ml), and NaNH₂ (10.3 g) which had previously been stirred at 30-40° for 30 min. The product was heated under reflux for 12 hr, then decomposed with H₂O and extracted with aqueous HCl. The base (70 g), recovered as usual, was a mixture of the cyanides 2a and 3a present in the ratio of 1.0:1.5, respectively (from integrals of the two N-methyl and secmethyl pmr signals). Petroleum ether (bp 60-80°) was added to the mixture and the solid which separated was recrystallized from C₆H₆-petroleum ether to give the 3-methyl cyanide 2a (28 g), mp 97-99°. Anal. (C₂₆H₂₈N₂) C, H, N, equiv wt.

The residues in the mother liquors gave a distillate, bp 198-200° (0.1 mm), which solidified on storage and was recrystallized from EtOH-Me₂CO to give the 2-methyl cyanide **3a** (30 g), mp 72-74°. Anal. (C₂₆H₂₈N₂) C, H, N, equiv wt.

4,4-Diphenyl-6-methylphenethylamino-3-heptanone.—The cyanide 2a (9.25 g) in toluene (60 ml) was treated with EtMgBr, prepared from EtBr (8.4 g) and Mg (1.8 g), in the usual manner to give the amino ketimine 2b (8.5 g), bp $202-205^{\circ}$ (0.05 mm), $\nu_{\rm max}$ 1710 (w) and 1632 cm⁻¹ (m). It was heated with 10% HCl (50 ml) on a steam bath for 30 min and the recovered base was distilled to give the amino ketone 2c (7.5 g), bp $188-190^{\circ}$ (0.05 mm), $\nu_{\rm max}$ 1710 cm⁻¹ (s). Anal. (C₂₈H₃₃NO) C, H, N.

It gave a hydrochloride dihydrate, mp 108-110°, from Me CO-Et₂O, ν_{max} 3350 cm⁻¹ (H₂O). Anal. (C₂₈H₃₄ClNO·2H₂O) C, H, N. 4,4-Diphenyl-5-methyl-6-methylphenethylamino-3-hexanone.

-The cyanide **3a** (9.25 g), treated with EtMgBr as described above, gave the amino ketimine **3b** (9.5 g), $\nu_{\rm max}$ 1720 (w) and 1631⁻¹ (m), which was hydrolyzed by a 10-hr reflux period with concentrated HCl (60 ml). The recovered base was distilled to give the amino ketone **3c** (8.5 g), bp 192-194° (1 mm), $\nu_{\rm max}$ 1710 cm⁻¹ (s). Anal. (C₂₈H₃₈NO) C, H, N.

 α -Dibenzylamino-N-phenylpropionamide (6).—A mixture of α -bromo-N-phenylpropionamide (22.8 g), dibenzylamine (19.7 g), K₂CO₃ (41 g), and Me₂CO was heated under reflux for 48 hr, then filtered, and the filtrate was evaporated. The residue was recrystallized from 70% EtOH to give the amino amide 6 (25.5 g), mp 80-82°. Anal. (C₂₃H₂₄N₂O) C, H, N, equiv wt.

N-[2-(Dibenzylamino)propyl]propionanilide (7).—The amino amide **6** (34.4 g) was reduced with LAH (7.6 g) by the procedure of Wright, *et al.*,² to give the diamine **7** (25 g), bp 190-192° (0.1 mm). *Anal.* ($C_{24}H_{26}N_2$) C, H, N, equiv wt.

It formed a monohydrochloride monohydrate, mp 90-92°, from EtOH-Et₂O, ν_{max} 3500 cm⁻¹ (H₂O). Anal. (C₂₃H₂₇ClN₂H₂O) N, equiv wt.

N, equiv wt. The diamine 7 (3.5 g) with propionic anhydride (7 ml) gave the **basic anilide 1c** (3 g), bp $210-212^{\circ}$ (0.1 mm). Anal. (C₂₆H₃₀-N₂O) C, H, N, equiv wt.

It formed a hydrochloride, mp 170-171°, from EtOH-Et₂O. Anal. (C₂₆H₃₁ClN₂O) C, H, N, equiv wt.

Alkylation of propionanilide (3 g) with 2-chloro-1-dibenzylaminopropane¹³ (5.8 g) by a reported methods also gave the basic anilide 1c (3 g), hydrochloride mp and mmp 170-171°.

Pmr spectra were recorded on Varian A-60 and Perkin-Elmer R-10 instruments in $CDCl_s$ with TMS as standard. The pK_s'

values of the basic anilides were measured in 50% EtOH-H₂O by Albert and Sergeants' method.¹⁴

Configurational Influences in Methadol and Normethadol Analgetics

A. F. CASY AND M. M. A. HASSAN

Faculty of Pharmacy, University of Alberta, Edmonton, Alberta

Received January 19, 1968

The greater analysic potency of α -(-)-methadol compared with its *dextro* enantiomorph has long been an awkward anomaly in the study of configurational relationships among diphenylpropylamine analgetics, due to the fact that the more active α -methadol is derived from the weak analgetic dextro methadone rather than the potent levo form.^{1,2} Evidence of the configuration of the secondary alcoholic center (C-3) of the methadols, lacking when attention was first drawn to this irregularity,³ is now available^{4,5} and it appears from these data (Table I) that the C-3 rather than the C-6 configuration is of prime importance respecting the activities of these alcohols. Thus the two most active methadols $[\alpha \text{ and } \beta \cdot (-)]$ both have the 3S configuration while the C-3 center of the most active isomethadol $[\beta - (+)]^6$ belongs to the same steric series.⁷ It was felt that support for this contention could be obtained by a study of methadol enantiomers lacking asymmetry at C-6 since it follows, from this view, that the S member of such a pair should be the more potent analgetic.

The required compounds 1b, termed here normethadols in accord with the designation "normethadone" applied to the same analog of methadone⁸ were obtained by reducing the norketone with LAH. Fractional crystallization of the (+)-tartrates gave the pure (+)-normethadol enantiomer while hydrochlorides of (\pm) - and (+)-normethadyl acetates were formed directly from the alcohols and acetyl chloride. Evidence for the configuration of (+)-normethadol was obtained by comparison of its ord spectrum with that of α -(+)-methadol (6R:3R). The latter compound has two asymmetric centers but it may reasonably be assumed that the center closer to the phenyl chromophore (*i.e.*, C-3) will largely determine the sign and fine structure of the Cotton effect. Hence ord characteristics should reflect C-3 stereochemistry in both compounds. It is to be noted that the two Cotton effects (Figure 1) not only have the same sign (positive) but also correspond closely in both peak positions and

⁽¹²⁾ Where analyses are indicated only by symbols of the elements, analytical results obtained for those elements were within $\pm 0.4\%$ of the theoretical values.

⁽¹³⁾ M. M. A. Hassan in footnote d, Table I.

⁽¹⁾ N. B. Eddy, E. L. May, and E. Mosettig, J. Org. Chem., 17, 321 (1952).

⁽²⁾ As part of this study, α -(+)- and α -(\pm)-methadol were submitted to Dr. P. Janssen (Janssen Pharmaceutica) for hot-plate assay since it was felt desirable to confirm the original results. The new data (ED₅₀ 30 mg/kg for α -(+)- and 22 mg/kg for α -(\pm)-methadol in mice, subcutaneous route) confirm that α -(-)-methadol is the more potent enantiomorph. Thanks are due to Dr. Janssen for these results.
