(Received May 8th, 1981)

Summary

Several isomers of the type $[M_2Cl_5L_4]$ (M = Ru, L = AsPh₃, As(p-tol)₃, As-(p-PhCl)₃, PEt₂Ph, PMe₂Ph; L₂ = Ph₂As(CH₂)₂AsPh₂; M = Os, L = PPh₃, AsPh₃) have been synthesised by various routes and characterised by magnetic, ESR and electrochemical measurements, and for $[(PEt_2Ph)Cl_2RuCl_3Ru(PEt_2Ph)_3]$ by X-ray structural analysis.

It is well established that whereas the reaction of "RuCl₃xH₂O" with an excess of PPh₃ in refluxing methanol gives [RuCl₂(PPh₃)₃] [1], a similar reaction with AsPh₃ [1] or As(p-tol)₃ [2] gives the ruthenium(III) methanolates [RuCl₃(AsR₃)₂MeOH]. Recent electrochemical studies on the latter [2] strongly indicate that facile rearrangement to the double chloride bridged complexes [Ru₂Cl₆(AsR₃)₄] occurs at room temperature in CH₂Cl₂, whereas thermolysis in C₆H₆ (or treatment of [Ru₂Cl₆(AsR₃)₄] with HBF₄), produced the triple chloride bridged complexes [(AsR₃)₂ClRuCl₃RuCl₂(AsR₃)] [3] which are the most oxidized members of stepwise Ru₂(II,III) to Ru₂(III,III) electron-transfer series.*

In contrast, Poddar and Ugarwala [4] reported in 1973 that refluxing "RuCl₃xH₂O" and an excess of AsPh₃ in butan-2-ol for several hours under nitrogen gave a brown solid (A) of composition $\{RuCl_2(AsPh_3)_2\}_n\}$. On the basis of analytical and magnetic data, ESR and electrochemical evidence, we suggest that this product A should be reformulated as the binuclear $\{Ru_2Cl_5\}$

^{*}Further electrochemical studies show that the two cyclic voltammetric waves observed at +0.62 and -0.44 V represent successive reductions of [Ru₂Cl₆(AsPh₃)₃], rather than one-electron oxidation and one-electron reductions as first believed [3]. The behaviour of [Ru₂Cl₆(As(p-tol)₃)₃], reducing at +0.58 and -0.44 V, confirms this pattern.

(AsPh₃)₄] complex with a formal II,III oxidation state. Thus, cyclic voltammetric (CV) and alternating current voltammetric (acV) studies on A in CH₂Cl₂/0.50~M Bu₄NBF₄ at 20°C unequivocally show a one-electron, reversible oxidation (+0.90 V)* and a one-electron reversible reduction (+0.14 V) step (separation 0.76 V), which are incompatible with the formation of a binuclear Ru₂-(II,II) complex. Magnetic measurements at ambient temperature give a value of $\mu_{\rm eff}$ 1.75 BM corresponding to that expected for one unpaired electron/molecule. Furthermore, the product exhibits a strong rhombic ESR spectrum in CH₂Cl₂ at 77 K (g_1 2.32; g_2 2.03; g_3 1.76) which indicates the absence of a plane of symmetry in the complex and hence configuration I (L = AsPh₃) is proposed.

The analogous red-brown complex $[Ru_2Cl_5\{As(p\text{-tol})_3\}_4]$ (I, L = Astol₃) $(E_{1/2} + 0.83 \text{ V (oxidation)}; +0.10 \text{ V (reduction)}; g_1 2.41; g_2 2.11; g_3 1.87)$ can be obtained as the major product**(A') by reaction of "RuCl₃xH₂O" with an excess of As(p-tol)₃ in ethanol. However, reaction of "RuCl₃xH₂O" with an excess of As(p-tol)₃ in butan-2-ol yields a yellow-green product B, also of stoichiometry $[Ru_2Cl_5\{As(p\text{-tol})_3\}_4]$ ($\mu_{\text{eff}} = 2.27 \text{ BM at } 291 \text{ K}$) which was shown by CV and acV studies to be quite distinct from A' with more difficult one-electron reversible oxidation (+1.24 V) and reduction (-0.26 V) steps. Furthermore, the ESR spectrum of B at 77 K in CH₂Cl₂ revealed an axial g-value pattern ($g_{\perp} 2.54; g_{\parallel} 1.63$), indicative of a plane of symmetry in the complex which is compatible with either configuration II or III. Figure 1 emphasises the dramatic dependence of electrochemical behaviour on the isomer form of these mixed valence $[Ru_2Cl_5(As-p\text{-tol}_3)_4]$ compounds.

The $E_{\frac{1}{2}}$ values and separation between oxidation and reduction waves (1.50 V) for B are very similar to those found for the previously reported [Ru₂Cl₅-(PEt₂Ph)₄] (+1.27 and -0.28 V, separation 1.55 V [3]); the latter also exhibits

^{*}All $E_{1/2}$ values are measured with respect to Ag/AgI reference electrode at which ferrocene is oxidised at ± 0.60 V.

^{**}ESR and electrochemical studies also reveal that a small amount of isomer II (see text) is present in the reaction mixture.

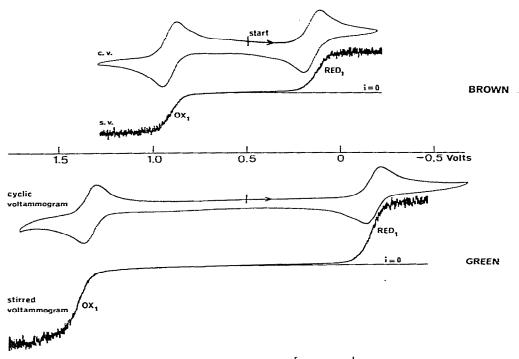

Fig. 1. Voltammetry of geometrical isomers of $[Ru_2Cl_5\{As(p-tol)_3\}_4]$ in $CH_2Cl_2/0.50\ M\ Bu_4NBF_4$ at 20°C vs. Ag/AgI. (Scan rate 100 mV s⁻¹).

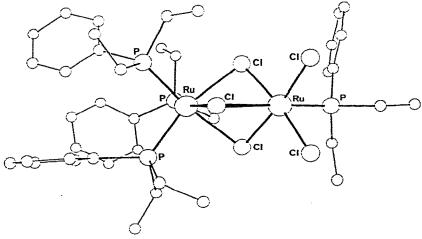

Fig. 2. Molecular geometry of [(PEt₂Ph)Cl₂RuCl₃Ru(PEt₂Ph)₃I, Ru-Ru 3.28 Å, angle RuClRu 82.9°.

a two g-value ESR pattern (g_{\perp} 2.46; g_{\parallel} 1.63) with $\mu_{\rm eff}$ 1.83 BM at 293 K. X-ray structural analysis of this compound has now confirmed this formulation and shows the asymmetrical structure II (Fig. 2) with three tertiary phosphines sharing a triangular face*. Since [(PEt₂Ph)Cl₂RuCl₃Ru(PEt₂Ph)₃] is synthesised

^{*}Crystal data for Ru₂Cl₅(PPhEt₂)₄ *MeNO₂: triclinic, space group $P\overline{1}$: a 12.835, b 14.353, c 30.597 Å, a 75.04, β 76.46, γ 65.87°. There are two very similar molecules in the asymmetric unit.

by aerial oxidation of [(PEt₂Ph)₂ClRuCl₃Ru(PEt₂Ph)₃] in hydrochloric acid/nitromethane, the exclusive formation of configuration II is indicative of selective oxidation of the "harder" RuCl(PEt₂Ph)₂ end of the Ru₂(II,II) binuclear compound, accompanied by substitution by further chloride.

Previously [3], we suggested that the large difference between the redox couples in $[Ru_2Cl_5\{As(p\text{-tol})_3\}_4]$ (I) and $[Ru_2Cl_5(PEt_2Ph)_4]$ (II) might be ascribed to the variations in the π -acid character of the $As(p\text{-tol})_3$ and PEt_2Ph ligands. However, now that it is appreciated that different isomeric forms are involved, the observed electrode potentials are understood to reflect quite simply the environment of the particular metal centre engaged in each Ru(II)/Ru(III) couple.

Similarly, the product from reaction of "RuCl₃xH₂O" with As(p-PhCl)₃ in methanol, of stoichiometry [Ru₂Cl₅{As(pPhCl)₃}₄], shows a reversible oxidation at 1.26 V and a quasi-reversible reduction at -0.42 V (separation 1.68 V) and an axial ESR pattern (g_1 2.48, g_{\parallel} 1.76) indicative of configuration II, while aerial oxidation of [Ru₂Cl₄(PMe₂Ph)₅] in HCl/CH₃NO₂ gives [Ru₂Cl₅(PMe₂Ph)₄] (II) with $E_{1/2}$ +0.81, -0.76 V (separation 1.57 V).

Similar mixed-valence binuclear complexes can be obtained with bidentate ligands. For example, reaction of "RuCl₃xH₂O" with Ph₂As(CH₂)₂AsPh₂ (dpae) (1/1 molar ratios) in butan-2-ol gave a product analysing closely for [Ru₂Cl₅-(dpae)₂]. Electrochemical studies showed two reversible oxidations at +0.10 and +0.26 V of unequal height with corresponding reversible reductions at -0.40 and -0.64 V. The separations between these redox couples are 0.50 V (major component) and 0.90 V, respectively, and the ESR spectrum of the product in CH₂Cl₂ at 77 K contains both a rhombic pattern (g_1 2.29, g_2 2.08, g_3 1.93) and a less prominent axial pattern (g_1 2.29, g_{\parallel} 1.74) thus strongly suggesting that both isomers I and III have been formed.

Finally, preliminary studies reveal that mixed valence binuclear complexes $[Os_2Cl_5L_4]$ ($L=PPh_3$, $AsPh_3$) can be formed from $Na_2[OsCl_6]$. Hence, reaction of $Na_2[OsCl_6]$ with an excess of PPh_3 in butan-2-ol gives first an orange-brown precipitate and later a green precipitate. The latter is the well-known $[OsCl_2-(PPh_3)_3]$ [5] and the former, which analyses well for $[Os_2Cl_5(PPh_3)_4]$ (μ_{eff} 2.14 BM at 291 K), shows reversible one-electron reduction (-0.06 V) and one-electron oxidation (+0.50 V) waves. Unfortunately the ESR spectrum was uninformative due to the excessive line broadening characteristic of osmium even at 77 K but the small separation favours a configuration of type I or III.

Reaction of Na₂[OsCl₆] with an excess of AsPh₃ in butan-2-ol also gave two products. The first orange-brown precipitate analysed for [OsCl₄(AsPh₃)₂] and exhibited a reversible one electron reduction wave at +0.45 V. The second redorange precipitate which analysed for [Os₂Cl₅(AsPh₃)₄] ($\mu_{\rm eff}$ 1.87 BM at 291 K) showed a reversible oxidation at +0.60 V and a reversible reduction step at -0.78 V. The large separation of 1.38 V would suggest that the asymmetrical isomer of type II has been formed but again ESR spectra were unhelpful.

Further work is now in progress to extend those studies to include other mono- and bi-dentate ligands and also to characterise and ultimately isolate some of these compounds in their less stable electrogenerated redox states. Acknowledgements. We thank the SRC for provision of electrochemical equipment, and for financial support (AJL), CONACYT, Mexico for financial support (RC), Dr. K. Suckling of the Department of Biochemistry, University of Edinburgh for ESR and Dr. G. Hunter of Dundee University for magnetic measurements, and Johnson-Matthey Ltd. for generous loans of ruthenium trichloride and sodium hexachloroosmate (IV).
