INDIRECT OXIDATIVE DEAMINATION OF BENZYLAMINES TO BENZALDEHYDES

Koon Ha Park* and Jae Bum Lee

Department of Chemistry, Chungnam National University,
Dae Jeon, Korea 305-764

Abstract: Treatment of N-benzylarenesulfonamide (**1**) with potassium superoxide yields benzaldehyde (**2**) and arenesulfonamide (**3**).

Deamination of benzylamine to benzaldehyde is achieved, in most cases, indirectly using various oxidants to make corresponding imines which could then be hydrolyzed in acidic conditions.¹⁻³ We report a simple and convenient indirect method for the conversion of benzylamine to benzaldehyde (Scheme 1). As shown in Scheme 1, N-benzylarenesulfonamide (**1**)⁴ prepared from benzylamine and arenesulfonyl chloride gives benzaldehyde (**2**), an oxidatively cleaved product, and arenesulfonamide (**3**) in the presence of potassium superoxide⁵⁻⁷ at room temperature.

Scheme 1

A general procedure of the present methodology is as follows: In a round-bottomed flask (50 mL) containing dry tetrahydrofuran (25 mL), equipped with a condenser connected to gas bubbler and a magnetic stirrer, potassium superoxide (510 mg, 57 mmol) was introduced. While passing oxygen-free nitrogen from the bottom of the solution, N-benzylbenzenesulfonamide (470 mg, 19 mmol) was added. Soon vigorous formation of oxygen⁸ ensued for about 15 seconds and then subsided. During the whole reaction period, no liberation of heat was observed. As the reaction proceeded, concentration of both benzaldehyde and benzenesulfonamide⁹ increased at the expense of N-benzylbenzenesulfonamide, determined by G. C. and ¹H NMR spectra.

Two points can be noted from the results of this reaction (in Table 1). One is that the present method (Scheme 1) is limited and unique only to N-benzylarenesulfonamides (entry 1-6, Table 1) in reaction with

Table 1. Synthesis of Benzaldehyde from the Reaction of N-Benzylbenzenesulfonamide and Related Compounds with KO_2

Entry	Substrate	Product	Reaction Time(hr)	Yield* (%)

*: Determined by either G. C. or ^1H NMR spectrum.

potassium superoxide to give benzaldehyde and arenesulfonamide. Other compounds such as N-phenylbenzenesulfonamide (entry 7), N-hexylbenzenesulfonamide (entry 8), N-benzylbenzamide (entry 9), and dibenzylamine (entry 10) are inert in these reaction conditions. The other is the facile and unusual N-C bond cleavage of compound **1** by potassium superoxide. It is described in the literature that structure of compound **1** is quite stable to acid or base. In forcing conditions, however, S-N bond is usually cleaved rather than N-C bond.^{10,11} In conclusion the unusual cleavage of N-benzylarenesulfonamide (**1**) by potassium superoxide (Scheme 1) presents an alternative methodology for the indirect oxidative deamination of benzylamine.

Mechanistic view points of this method are currently under investigation.
