Received July 18, 2007

Propargyl carboxylates react with 1,3-dicarbonyl compounds and electron-rich arenes in the presence of Au(I) catalysts to give enol carboxylates via  $\alpha$ , $\beta$ -unsaturated Au(I) carbenes or Au(I)-coordinated allenes formed by 1,2- or 1,3-acyl migration, respectively.

Propargyl esters **1** undergo 1,2- or 1,3-acyl migration with Au(I) complexes via intermediates **2** to form highly reactive  $\alpha,\beta$ -unsaturated Au(I) carbenes **3** or Au(I)-coordinated allenes **4**, respectively (Scheme 1).<sup>1-3</sup> Complexes **4** are usually depicted in a simplified form as Au(I)-coordinated allenes **4'**.<sup>4</sup> Similar pathways take place with other metal catalysts.<sup>1,2,5,6</sup>

Carbenes **3** formed by 1,2-acyl migration of **1** react with alkenes to give cyclopropanes.<sup>3b</sup> Au(I) carbenes formed from 1,6-enynes have also been trapped in cyclopropanation reactions.<sup>7</sup> Recently the Au(I)-catalyzed addition of electron-

rich aromatic compounds to 1,6-enynes has been reported.<sup>8</sup> Although the main course of this reaction is the nucleophilic attack at the cyclopropane of intermediate cyclopropyl Au-(I) carbenes, we have observed two cases of attack to the carbene with indole as the nucleophile.<sup>8b,9</sup>

Here we report that propargyl esters **1** react with 1,3dicarbonyl compounds and electron-rich arenes by trapping

and Z isomers was obtained with AuCl and AuCl<sub>3</sub> (Table 1, entries 1 and 2), whereas cationic Au(I) catalysts provided pure Z-5a. The reaction was faster and cleaner with complex 8 (Table 1, entries 3 and 4). With 10 and Ag(I), a mixture of 5a and the product of nucleophilic substitution  $13^{12}$  was obtained (Table 1, entry 6). Reaction of 1a with cationic complex 11 or Sc(OTf)<sub>3</sub> as catalysts gave acetylene 13, whereas with Cu(OTf)<sub>2</sub>, a mixture of 13 and the product of hydration of the alkyne (2-benzoyl-1,3-diphenylpentane-1,4dione) was obtained (Table 1, entries 7–9). With AgSbF<sub>6</sub> (5 mol %), this trione was obtained in 97% yield.<sup>13</sup> Interestingly, propargyl alcohols have been shown to react with allylsilanes in the presence of AuCl<sub>3</sub> and other gold catalysts by nucleophilic substitution.<sup>14</sup>

<sup>(4)</sup> Structure 4 is more consistent with calculations: Lemière, G.; Gandon, V.; Cariou, K.; Fukuyama, T.; Dhimane, A.-L.; Fensterbank, L.; Malacria, M. *Org. Lett.* **2007**, *9*, 2207–2209.

<sup>(13)</sup> See Supporting Information for details.

Propargyl esters 1a-d react with a variety of carbon nucleophiles with catalyst 8 (Table 2). In the reactions with these substrates, which bear phenyl or gem-dimethyl substituents at the propargyl position, products of 1,2-addition via intermediates 3 were obtained. A higher yield was obtained in the reaction of benzoate 1b (Table 2, entry 2) than that obtained with acetate 1a under identical conditions (Table 1, entry 2). The addition of  $\beta$ -ketoester 14a to 1b had to be carried out in the presence of  $Sc(OTf)_3$  (5 mol %) to give adduct 5d in moderate yield (Table 2, entry 3). In the reaction of 1c with indole (15), the initial product suffered isomerization of the olefin to form 5e (Table 2, entry 4), whereas 1d and 15 gave a mixture of 5h/5h' (Table 2, entry 7). Z-Isomers 5a-e and 5h appear to be obtained under kinetically controlled conditions, as their E-isomers are slightly more stable (PM3 calculations).

Reaction of **1a** with 1,3,5-trimethoxybenzene (**16**) and catalyst **8** gave the expected product of 1,2-addition to the gold carbene **5i** (44%) along with **6a** (6%), which corresponds to a product of 1,4-addition to intermediate **3** (Scheme 2). A product of this type, **6b**, was obtained in 76% yield

from propargyl benzoate **1e** using catalyst **9**. A product of 1,4-addition was also obtained in the reaction between **1e** and keto aldehyde **12c**, although in this case the nucleophile reacts at oxygen to give enol ether **6c** (60%).

Reactions of 1e-g with diketones 12a or 12d or  $\beta$ -ketoesters 14b-d in the presence of 8 or 9 as catalysts afford products resulting from 1,3-acyl migration via intermediates 4 (Table 3). Addition of 5 mol % of Sc(OTf)<sub>3</sub> or Cu(OTf)<sub>2</sub> led to improved results with  $\beta$ -ketoesters as nucleophiles. In the reaction of 1f with 12a, a 1.1:1 mixture of 7d and 7d' was obtained (Table 3, entry 5) as a result of nonregiose-

<sup>*a*</sup> 2 mol % of  $9/AgSbF_6$  and 5 mol % of  $Cu(OTf)_2$ .<sup>*b*</sup> 5 mol % each of 9 and  $AgSbF_6$ . <sup>*c*</sup> 2 mol % of 8. <sup>*d*</sup> 2 mol % of 8 and 5 mol % of Sc(OTf)\_3. Compounds **7a-c** and **7e**,**f** are 1.1–1.2:1 mixtures of diastereomers.

lective attack of the nucleophile to **4**. The trans configurations of **7a**-**g** were assigned on the basis of the observed olefinic  ${}^{3}J$  of 12.3–12.6 Hz.<sup>15</sup> It is important to note that in the presence of Sc(III) or Cu(II) as additives the major reaction pathway is dominated by Au(I). Thus, the reaction of **1g** with **14d** did not proceed with Sc(OTf)<sub>3</sub> or Cu(OTf)<sub>2</sub> (5 mol %) in the absence of Au(I).

<sup>(14)</sup> Georgy, M.; Boucard, V.; Campagne, J.-M. J. Am. Chem. Soc. 2005, 127, 14180–14181.

Reaction of 2-butynyl acetate (1h), with a disubstituted alkyne, was examined with arene 16 as the nucleophile (Scheme 3). In this case, reaction with catalyst 8 gave a ca. 2:1 mixture of 5j and 7h in a combined 59% yield.

Experiments with deuterated substrates  $12a-d_2$  and  $1g-d_1$  are shown in Scheme 4. These results are consistent with the mechanistic hypotheses shown in Scheme 1 in which

the enol of the 1,3-dicarbonyl compound or the arene adds to intermediates 3 or 4.

Although the factors that control the regioselectivity of the addition are still not totally understood, propargyl carboxylates bearing phenyl or *gem*-dimethyl groups at C-3 lead to products **5** of 1,2-addition to  $\alpha$ , $\beta$ -unsaturated Au(I) carbenes **3**, whereas propargyl carboxylates with a methyl group or no substituents at that position give adducts **6** or **7**. However, substrates **1a** and **1h** also give products of 1,2addition, **5i** and **5j**, in their reactions with **16** (Schemes 2 and 3), which suggests that a different mechanism takes place in these cases.

In summary, we have found that  $\alpha,\beta$ -unsaturated Au(I) carbenes **3** or Au(I)-coordinated allenes **4** formed from propargyl esters are trapped by 1,3-dicarbonyl compounds and electron-rich arenes. This is a simple procedure for the formation of functionalized enol carboxylates under mild conditions. It is worth noting that in contrast with oxophilic Lewis acids that lead to nucleophilic substitution with propargyl carboxylates Au(I) promotes the nucleophilic addition to these substrates.
