A Bioinspired Synthesis of (\pm)-Rubrobramide, (\pm)-Flavipucine, and (\pm)-Isoflavipucine

Shoma Mizutani, Kenta Komori, Tohru Taniguchi, Kenji Monde, Kouji Kuramochi,* and Kazunori Tsubaki

Abstract: A biomimetic synthesis of naturally occurring lactams rubrobramide, flavipucine, and isoflavipucine is described. The key step is a regioselective Darzens reaction between isobutyl glyoxal and an α -bromo- β -ketoamide. The construction of the core tricyclic ring system of rubrobramide was achieved by a cascade reaction in a single step from an α,β epoxy- γ -lactam. Furthermore, the absolute configuration of naturally occurring (+)-rubrobramide was determined by vibrational circular dichroism. (\pm)-Flavipucine and (\pm)isoflavipucine were synthesized from an epoxyimide, which was prepared by reaction of isobutyl glyoxal with a protected α -bromo- β -ketoamide. Deprotection of the epoxyimide and formation of the pyridone ring gave (\pm)-flavipucine, which was converted into (\pm)-isoflavipucine by thermal isomerization.

Rubrobramide (1), which has a highly oxidized ring system, was first isolated from the culture filtrate of *Cladobotryum rubrobrunnescens* (Figure 1).^[1] Although rubrobramide is an optically active metabolite { $[\alpha]_D + 177$ (*c* 1.0, CHCl₃)}, its absolute configuration has not yet been determined. This

Supporting information for this article can be found under: http://dx.doi.org/10.1002/anie.201602910. compound is structurally related to flavipucine (2), which was isolated from the same fungus.^[2] (-)-Flavipucine [(-)-2] has been isolated from *Aspergillus flavipes*,^[3] as well as the fungus-caused *Macrophoma* fruit rot.^[4] (+)-Flavipucine [(+)-2] has been isolated from the culture extract of *Phoma* sp.^[5] The absolute configuration of (+)-2 was determined to be *S*,*S* by comparison of the experimental and calculated circular dichroism (CD) spectra.^[5] Interestingly, an optically inactive form of (\pm) -isoflavipucine $[(\pm)-3]$ has been isolated from *Aspergillus flavipes*^[6] and *Phoma* sp.^[5] produced by rearrangement of optically active (-)- or (+)-2.^[5-7] It has been proposed that the natural products **1**–3 are biogenetically produced by a hybrid polyketide synthase (PKS) and non-ribosomal peptide synthetase (NRPS) system (Scheme 1),

Scheme 1. Proposed biosynthesis of 1-3.

although the detailed biosynthetic pathways, especially for the synthesis of rubrobramide, remain unclear.^[8] The amide **4** is formed from acetyl CoA, malonyl CoA, and leucine by PKS-NRPS. Dieckmann condensation of **4** affords **5**, which can be oxidized to yield the key intermediate **6**. Construction of the tricyclic ring from **6** then gives (+)-**1**. Hydrolysis of the key intermediate **6**, followed by transamidation of the resultant product **7** leads to the pyridone **8**. Epoxidation of **8** gives (-)- or (+)-**2**, which can rearrange to (\pm)-**3**. The interesting biosyntheses of **1**-**3** motivated us to start synthetic studies of these natural lactams. Herein, a bioinspired approach to the total syntheses of (\pm)-**1**-**3** is described. Furthermore, determination of the absolute configuration of naturally occurring (+)-**1** by the exciton chirality method

These are not the final page numbers!

using vibrational circular dichroism (VCD)^[9] is also described.

Our retrosynthetic analysis of (\pm) -1, (\pm) -2, and (\pm) -3 is shown in Scheme 2. The compound (\pm) -1 is prepared from γ -

Scheme 2. Retrosynthetic analysis of (\pm) -1–3.

lactam 9 via an intramolecular oxy-Michael addition of the hydroxy group to the enone. The compound 9 is synthesized by deprotection of the ketal in 10a, followed by an intramolecular epoxide-opening reaction. The compound 10a would be prepared by Darzens reaction of isobutyl glyoxal (11)^[10] with the α -bromo- β -ketoamide 12.^[11] The compounds (\pm)-2 and (\pm)-3 are prepared from the epoxyamide 13, which is prepared by removal of the *tert*-butoxycarbonyl (Boc) group in 14, which comes from deprotection of the ketal in 15. The epoxyimide 15 is prepared by a Darzens reaction between 11 and 16.

The syntheses of **12** and **16** are shown in Scheme 3. The ketone in $17^{[12]}$ was protected as a 1,3-dioxolane to give **18**.^[13] Subsequent amidation with hexamethyldisilazane (HMDS), and bromination of **19** with *N*-bromosuccinimide (NBS) in the presence of sodium hydrogen sulfate^[14] afforded **12**. Similarly, amidation of **18** with *tert*-butyl carbamate, followed by bromination of the resultant **20**, afforded **16**.

The synthesis of (\pm) -1 is shown in Scheme 4. Darzens reaction between 11 and 12 in the presence of triethylamine gave the tautomers 10 a/b. The ¹H NMR spectrum of the crude reaction mixture indicates that it exists mainly as a mixture of cyclic hemiaminal diastereomers 10 a (d.r. = 4:1) with the open-chain tautomer 10b as the minor component (10 a/10 b = 8:1). The compounds 10 a/b were unstable and decomposed during purification. Thus, the crude reaction mixture was used in the next reaction without purification. Treatment with *p*-toluenesulfonic acid monohydrate (*p*-TsOH·H₂O) in CH₂Cl₂ for 19 hours afforded (\pm)-1 in 19% yield over the two steps. The ¹H and ¹³C NMR spectra for synthetic (\pm)-1 are in agreement with those reported for natural 1.

Scheme 3. Synthesis of the α-bromo-β-ketoamides 12 and 16. Reagents and conditions: a) 1,2-Bis(trimethylsiloxy)ethane (2.0 equiv), TMSOTF (1.0 equiv), CH_2Cl_2 , -20 °C, 2 d, 93 %; b) HMDS (1.0 equiv), CH_2Cl_2 , reflux, 30 min, 77%; c) NBS (0.95 equiv), NaHSO₄ (0.42 equiv), THF, 0 °C, 15 min, 90%; d) BocNH₂ (1.0 equiv), CH_3CN , 30 min, 85%; e) NBS (0.95 equiv), NaHSO₄ (0.25 equiv), THF, 0 °C, 20 min, 81 %. Boc = tert-butoxycarbonyl, HMDS = hexamethyldisilazane, NBS = N-bromosuccinimide, Tf = trifluoromethanesulfonyl, THF = tetrahydrofuran, TMS = trimethylsilyl.

Scheme 4. Synthesis of (\pm) -rubrobramide [(\pm) -1]. Reagents and conditions: a) **11** (1.1 equiv), **12** (1.0 equiv), Et₃N (1.0 equiv), THF/H₂O (10:1), RT, 30 min, **10a/10b** (8:1), d.r. = 4:1 at the hemiaminal; b) *p*-TsOH·H₂O (0.3 equiv), CH₂Cl₂, RT, 19 h, 19% over two steps. Ts = 4-toluenesulfonyl, d.r. = diastereomeric ratio.

Scheme 5. Isolation of the key intermediates for the transformation of **10a** into (\pm) -1. Reagents and conditions: a) **11** (1.1 equiv), **12** (1.0 equiv), Et₃N (1.0 equiv), THF/H₂O (10:1), RT, 30 min, **10a/10b** (8:1), d.r. = 4:1 at the hemiaminal; b) *p*-TsOH·H₂O (0.3 equiv), CH₂Cl₂, RT, 30 min, **21** (18%), **22** (29%) over two steps.; c) *p*-TsOH·H₂O (1.0 equiv), acetone/H₂O (3:1), 70°C, 30 h, (\pm)-1 (22%), **22** (13%); d) *p*-TsOH·H₂O (1.0 equiv), acetone/H₂O (3:1), 70°C, 6 d, 76%.

Transformation of **10a** into (\pm) -**1** involved multiple transformations. Key intermediates were isolated during examination of the reaction conditions (Scheme 5). When **10a/b** were treated with *p*-TsOH·H₂O for 0.5 hours, the compounds **21** and **22** were obtained in 18 and 29% yield, respectively. Both **21** and **22** were characterized as an inseparable mixture of *E* and *Z* isomers (2:5). Treatment of **21** with *p*-TsOH·H₂O in acetone/H₂O (3:1) at 70°C gave (\pm) -**1** and **22** in 22 and 13% yields, respectively. Treatment of **22** under the same reaction conditions afforded (\pm) -**1** in 76% yield. These results indicate that both **21** and **22** are intermediates in the conversion of **10a** into (\pm) -**1** [see Scheme S1 in the Supporting Information for a proposed mechanism for the transformation of **10a** into (\pm) -**1**].

Scheme 6. Optical resolution of $[(\pm)-1]$. Reagents and conditions: a) (-)-camphanic chloride (1.0 equiv), DMAP (2.0 equiv), CH₂Cl₂, 4Å M.S., 0°C, 15 min, **23a** (42%), **23b** (42%); b) K₂CO₃ (1.0 equiv), MeOH, 0°C, (+)-1 (80%), (-)-1 (78%). DMAP = *N*,*N*'-dimethyl-4aminopyridine, M.S. = molecular sieves.

The optical resolution of (\pm) -1 was carried out to determine the absolute configuration of both enantiomers of 1 (Scheme 6). Esterification of (\pm) -1 with (-)-camphanic chloride afforded the diastereomers 23a and 23b, which were separated by column chromatography. Methanolysis of 23a and 23b under basic conditions gave (+)-1 and (-)-1, respectively. The specific rotations of (+)-1 and (-)-1 were +173.5 and -169.8 (c 0.1, CHCl₃), respectively. The absolute configuration of (+)-1 and (-)-1 were determined by the VCD exciton chirality method^[9,11] (Figure 2). The IR spectra of (+)-1 and (-)-1 showed strong absorptions at 1750 and 1721 cm^{-1} , representing the C=O stretching vibrations of the lactam at C6 and the ketone at C4, respectively (Figure 2a). The corresponding VCD signals in the C=O stretching region exhibited a strong bisignate pattern (Figure 2b). The VCD spectrum of (+)-1 showed a positive-negative couplet from the lower to higher frequencies, thus indicating a clockwise orientation between the two adjacent carbonyl groups at C4 and C6 (Figure 2c). This result suggests that the absolute configuration of naturally occurring (+)-1 is 2S,5R,7S,8S. Meanwhile, the negative-positive VCD couplet of (-)-1 in the C=O stretching region is indicative of the counterclockwise

Figure 2. Determination of the absolute configuration of (+)-1 and (-)-1. A) IR and B) VCD spectra of (+)-1 (red) and (-)-1 (blue). The IR and VCD spectra were measured in CDCl₃ (0.125 M for (+)-1 and 0.140 M for (-)-1, $l = 50 \mu$ m). C) Schematic structures for (+)-1 and (-)-1. The structures were optimized using the DFT B3LYP/6-311G-(d,p) method as implemented in the Gaussian 09 program.^[15]

orientation of the two carbonyl groups, by which the absolute configuration of (-)-1 is determined to be 2R,5S,7R,8R. These assignments were further supported by a comparison of the experimental and theoretical VCD spectra (see Figure S1 in the Supporting Information).

The synthesis of (\pm) -2 is shown in Scheme 7. A Darzens reaction between 11 and 16 gave the epoxyimide 15 in 89% yield with complete regioselectivity (Scheme 7 A). Treatment of 15 with a catalytic amount of PdCl₂(CH₃CN)₂^[16] in acetone afforded (\pm) -2 as the sole product in 67% yield. Formation of (\pm) -2 involved removal of the ketal in 15, removal of the Boc group in the resultant 14, and formation of the pyridone ring (Scheme 7B). Actually, the enol tautomer of 14 was obtained by treatment of 15 with [PdCl₂(CH₃CN)₂] in acetone/toluene (see Scheme S2 in the Supporting Information).

A one-pot synthesis of (\pm) -3 from 15 was also accomplished (Scheme 8). After treatment of 15 with PdCl₂-(CH₃CN)₂ in acetone for 4 days, toluene was added to the reaction mixture. The acetone was removed by heating at 70 °C for 1 hour, and the resultant reaction mixture was

Scheme 7. Synthesis of (\pm) -flavipucine $[(\pm)$ -2]. A) Synthesis of (\pm) -2. B) Proposed synthetic pathway from **15** to (\pm) -2. Reagents and conditions: a) **11** (1.2 equiv), **16** (1.0 equiv), Et₃N (1.0 equiv), THF/H₂O (10:1), RT, 2 h, 89%; b) PdCl₂(CH₃CN)₂ (0.3 equiv), acetone, 5 d, 67%.

Scheme 8. One-pot synthesis of (\pm) -isoflavipucine $[(\pm)$ -3] from epoxyimide 15. Reagents and conditions: PdCl₂(CH₃CN)₂ (0.3 equiv), acetone, 4 d, then toluene, 70°C, 1 h, followed by 160°C for 7 h, 50% over two steps.

heated at 160 °C under sealed conditions to give (\pm)-3 in 50 % yield.

In conclusion, a biomimetic synthesis of (\pm) -rubrobramide as well as structurally related (\pm) -flavipucine and (\pm) isoflavipucine has been achieved. Detailed reaction pathways from **10a** to (\pm) -rubrobramide, and from **15** to (\pm) -flavipucine were elucidated. Furthermore, both enantiomers of rubrobramide were obtained by optical resolution of a synthetic racemic sample. The absolute configuration of natural rubrobramide was determined to be 2*S*,5*R*,7*S*,8*S* by using the VCD exciton chirality method. We believe that the results obtained in this study will help elucidate the biosynthetic pathways of these lactam natural products.
