Synthetic Studies on Insect Hormones. VII.¹ An Approach to Stereospecific Synthesis of Juvenile Hormones²

Sir:

We wish to report a stereospecific synthesis of *trans*, cis-6-ethyl-10-methyldodeca-5,9-dien-2-one (I), a key intermediate in a synthesis³ of juvenile hormone (II).⁴

A scarcity of convenient methods for stereospecific synthesis of acyclic trisubstituted olefins led us to examine sequential fragmentation of a bicyclic precursor, VI. Control of olefin geometry is thereby transposed to control of relative stereochemistry in cyclic systems.

Consideration of the *trans* and *cis* olefin geometries in I dictates the required stereochemistry³ at four of the asymmetric centers in the chosen precursor VI. Configuration at the fifth center, C_{3a} , does not influence the geometry of olefin formation, but markedly affects the ease of concerted internal cleavage in VIb.

Synthesis of VI was commenced by Michael addition of 2-ethylcyclopentane-1,3-dione,⁶ in refluxing methanolic potassium hydroxide solution, to propyl vinyl ketone and *p*-toluenesulfonic acid catalyzed cyclization of the adduct in boiling benzene to afford IIIa⁷ [67%; bp 125–127° (0.08 mm)]. Selective reduction of the cyclopentanone carbonyl of IIIa with ethanolic sodium borohydride at 5° led stereospecifically to the required *cis*⁸ relationship between hydroxyl and angular ethyl in IIIb⁷ (88%; mp 61–62°).

(6) We are grateful to Dr. Herchel Smith for a generous gift of this compound.

(7) Satisfactory elemental analytical data were obtained for this substance.

(8) Cf. Z. G. Hajos, D. R. Parrish, and E. P. Oliveto, Tetrahedron, 24, 2039 (1968), and ref 6, 8, and 9 therein; H. Smith, et al., J. Chem. Soc., 4472 (1964); L. Velluz, et al., C. R. Acad. Sci., Paris, Ser. C, 257,

Protection of IIIb as a tetrahydropyran-2-yl ether (THP) allowed generation from IIIc (5 equiv of 0.37 *M* potassium *t*-butoxide in refluxing *t*-butyl alcohol) of the enolate anion which was alkylated from the less hindered α face⁹ by methyl iodide at 0° to afford IVa $[nmr, {}^{10} 0.81 (t, J = 7 Hz), 1.03 (t, J = 7 Hz, ethyl)$ CH₃), and 1.15 (s, 4α -methyl); 62 % from IIIa]. Stereoselectivity of alkylation was indicated to be 95% by gas chromatographic and nmr analyses of IVa and the derived acid hydrolysis product IVb [nmr, 1.14 (s, 4α methyl)]. Lithium tri-t-butoxyaluminum hydride reduction of IVb in refluxing tetrahydrofuran afforded a single crystalline diol, IVc7 [74%; mp 153-155°; nmr, 1.09 (s, 4 α -methyl), 3.33 (dd, $J_{aa} = 10$ Hz, 5 α -H)] with the necessary cis orientation of the new equatorial hydroxyl¹¹ relative to the 4β -ethyl group.

3086 (1963), similarly obtained the alcohol ii of proven stereochemistry from diketone i which is closely similar to IIIa.

(9) α Configuration of the 4-methyl in IVa is stated here for clarity but is assigned from the later finding that fragmentation through C-4 and C-5 in VIb gave stereospecifically a *cis* olefin which fixes⁵ the relative configurations at C-4 and C-5. Establishment of configuration¹¹ at C-5 then allowed assignment at C-4.

(10) Nmr spectra were recorded on a Varian HA-100 spectrometer using deuteriochloroform as solvent and are quoted as δ (parts per million) downfield from tetramethylsilane as internal standard. We wish to thank Miss J. Tremble and Dr. Phyllis Kaplan for these determinations.

(11) The β configuration of hydroxyl at C₅ follows from sequential conversion of IVc to a diacetate and a bromohydrin (a)⁷ (mp 144–146°) and chromous acetate-thiophenol reduction of the latter to a diacetoxy secondary alcohol (b)⁷ (mp 113–114°). Nmr spectra¹⁰ of compound

⁽¹⁾ Part VI: G. Hüppi and J. B. Siddall, Tetrahedron Letters, 1113 (1968).

⁽²⁾ Publication No. 348 from the Syntex Institute of Steroid Chemistry.

⁽³⁾ K. H. Dahm, H. Röller, and B. M. Trost, *Life Sci.*, 7, 129 (1968); K. H. Dahm, B. M. Trost, and H. Röller, *J. Am. Chem. Soc.*, 89, 5292 (1967).

Epoxidation of IVc with m-chloroperbenzoic acid in ether gave only α -epoxide⁷ (mp 158–160°), identical with the product from methanol-sodium hydroxide treatment of the bromohydrin¹¹ a, whereas epoxidation in dichloromethane at 5° allowed hydroxyl-assisted formation of the β -epoxide V⁷ (50%, mp 162–163°) from IVc.

Optimal geometry¹² for concerted cleavage of C_{3a} - C_4 and C₅-O bonds is attained in VIa⁷ (mp 133-135°), produced in 65% yield by lithium aluminum hydride reduction of V in refluxing dioxane. Treatment of the triol VIa with p-toluenesulfonyl chloride (5 equiv) in pyridine at 5° led selectively to the equatorial 5 β tosylate VIb (89%; $\nu_{\text{max}}^{\text{CCl}_4}$ 1600, 1360, 1180, and 1170 cm⁻¹) which underwent quantitative¹³ fragmentation on exposure to sodium hydride in dry tetrahydrofuran at 20° with formation of the cis-olefinic ketone VII $[\nu_{\text{max}}^{\text{CCl}_{4}} 1735 \text{ cm}^{-1}; \text{ nmr } 1.67 \text{ (d, } J = 1.5 \text{ Hz, vinylic}]$ CH_3) and 5.04 (t, J = 7.5 Hz, vinylic H); semicarbazone⁷ mp 144–145°]. Gas chromatographic and nmr analyses of VII did not reveal the presence of any trans isomer.

Alkylation of this ketone by ethereal methyllithium to form the diol VIIIa (57%; 3,5-dinitrobenzoate⁷ VIIIc mp 91-91.5°) was facilitated by temporary protection of the hydroxyl in VII as a tetrahydropyranyl ether. Reaction of the diol VIIIa with excess p-toluenesulfonyl chloride-pyridine was slow but gave cleanly the tosylate VIIIb (95%) which fragmented smoothly in the presence of sodium hydride in dry tetrahydrofuran to generate the central trans olefinic bond in trans, cis-6-ethyl-10-methyldodeca-5,9dien-2-one (I; 80% from VIIIb; $\nu_{max}^{CC_{14}}$ 1715 cm⁻¹; nmr 1.66 (d, J = 1.5 Hz, vinylic CH₃), 2.12 (s, COCH₃), 5.04 (m, 2-vinylic H), homogeneous by gas chromatographic¹⁴ analysis).

Assignment of cis geometry to the 9,10 double bond in I is based on the 1.66-ppm chemical shift of the vinylic methyl group. In this series the corresponding trans isomers consistently show³ vinylic methyl signals at 1.59-1.61 ppm.

The stereospecific formation of the central 5,6 double bond in I by fragmentation enables its geometry to be related directly⁵ to the configurations of angular

b show extreme deshielding of the methine proton at C5 (δ 5.41 ppm) by a hydroxyl at C₃, indicating a proximity possible only in a *cis*-hydrindan having 3α -hydroxyl and 5β -acetoxyl stereochemistry.

(12) Steric requirements for concerted fragmentation processes are discussed by C. A. Grob, H. R. Kiefer, H. Lutz, and H. Wilkens, *Tetra*hedron Letters, 2901 (1964)

(13) Under these conditions the $3a\alpha$ -hydroxy 5 β -tosylate d (mp dec) gave a cyclic ether (e) (85%) together with the cis olefin f 135 (15%). Methyllithium alkylation of compound f followed by acid

hydrolysis gave a diol identical with VIIIa.

(14) F & M Model 402, 4% Carbowax 20M on Diatoport S (2 m \times 3 mm) at 130°.

ethyl and secondary hydroxyl in VIIIa. Since the cis relationship of the latter groups in VIIIa was produced from IIIa by a borohydride reduction whose stereochemical course is well established⁸ in such systems, the 5,6 double bond of I can be assigned *trans* geometry.

Acknowledgment. The authors wish to thank Dr. J. H. Fried for helpful discussions.

A Highly Stereoselective Synthesis of the Racemic Juvenile Hormone

Sir:

In a series of brilliant investigations Dahm, et al.,1 have shown that the extremely potent substance responsible for arresting develoment at the pupa stage in Hyalaphora cecropia is methyl trans, trans, cis-10-epoxy-7-ethyl-3,11-dimethyl-2,6-tridecadienoate (1), called the juvenile hormone.2 Their published work has culminated in a total synthesis of the racemic hormone which, although not stereoselective, made available many of the stereoisomers and set the stage for the next major development, namely a stereoselective synthesis. We are reporting here on the realization of this aim.³ Our synthesis is based on an application of the highly stereoselective modification of the Julia method for producing trans-trisubstituted olefinic bonds⁴ which involves in the key step the rearrangement of a cyclopropylcarbinyl to the homoallylic system, as illustrated here by the conversion of the carbinol 5 to the bromide By this expedient we have developed a scheme 6. which affords the racemic juvenile hormone in 12 steps starting from methyl *trans-* γ -bromo- β , β -dimethylacrylate $(2)^{5}$ and 1-acetyl-1-ethylcyclopropane (3, R)H).⁶ At the present stage of development all but two of the steps (see below) proceed in 90% yield or better; thus the hormone is now relatively easily accessible.

Ketone 3 (R = H) was treated with dimethyl carbonate and sodium hydride. The sodio derivative of the resulting β -keto ester 3 (R = CO₂CH₃) was allowed to react with the bromo ester 2 in tetrahydrofuran at

90, 2882 (1968).

(5) I. Ahmad, R. N. Gedye, and A. Nechvatal, J. Chem. Soc., 185 968). We prepared the material readily by bromination of $\beta_i\beta_j$ -(1968).dimethylacrylic acid with N-bromosuccinimide. During the work-up the cis bromo acid underwent spontaneous lactonization, leaving the desired *trans* isomer as the only acidic material. The acid was easily esterified by the method of R. O. Clinton and S. C. Laskowski, J. Am. Chem. Soc., 70, 3135 (1948).

(6) This ketone was prepared by the method described for producing 1-acetyl-1-methylcyclopropane (M. Julia, S. Julia, T. S. Yu, and C. Newville, Bull. Soc. Chim. France, 1381 (1960)) except that ethyl instead of methyl iodide was used in the alkylation step.
