

2,2'-Biphenyleneammonium Salts

By D. HELLWINKEL* and H. SEIFERT

(Institut für Organische Chemie, Universität Heidelberg, 69 Heidelberg, West Germany)

IN 1963, Nesmeyanov¹ synthesised the first, and until now the only known tetra-arylammonium salt containing the 2,2'-biphenylylenediphenylammonium cation. In connection with our work

on spiro-compounds of the main group elements,² we prepared the bis-2,2'-biphenylyleneammonium cation (I) in a manner analogous to Nesmeyanov's (see Scheme).

(i) Diazotisation (KI) (42–51%); (ii) Carbazole-Cu; (iii) a, Reduction, b, Diazotisation (AcOH), c, heat;
 (iv) $\text{CH}_3\text{I}-\text{OH}^-$; (v) Reduction; (vi) Same as (iiib) and then heat.

The following salts with cation (II) were obtained and analysed:

X	I	Br	Cl	I_3	BPh_4	$\text{BF}_4\text{H}_2\text{O}$	HgI_3	Picr.	PVI†
M.p.	285–288°	319–321	325–328	221–222	286–291	280–282	206–208	229–230	283–286

† PVI = tris-2,2'-biphenylenephosphosphate anion.

With the same starting material,³ an alternate carbazolium salt, the 2,2'-biphenylenedimethylammonium cation (II), was easily synthesised. The iodide of (II) is rather unstable; it decomposes rapidly at its m.p. (100–102°) and more slowly when heated in solution up to about 70°, yielding quantitatively *N*-methylcarbazole (and

methyl iodide).⁴ The corresponding tetraphenylborate (decomp. 188–191°) and tetrafluoroborate (decomp. 220–222°) are more stable. The n.m.r. spectrum of the latter shows methyl resonance at τ 5.92 and an aromatic multiplet at τ 1.4–2.3. Investigations with (II) as a methylation agent are in progress.
