Trialkyl α -phosphonates were prepared by heating the alkyl α -bromo ester with a 100% molar excess of trialkyl phosphite at 160–190° in an atmosphere of nitrogen. The alkyl bromide formed was swept out and collected in a Dry Ice trap. The reaction was stopped when the weight of alkyl bromide became constant (usually 4–5 hr.). Generally, 90% of the calculated amount of alkyl bromide was obtained. The entire reaction mixture was then fractionally distilled to obtain the pure α -phosphonates (Tables I and II).

Hydrolysis Studies. (a) Dilute Acid.—The procedure described previously for the hydrolysis of acyloxyethylphosphonates was employed.⁶ The trialkyl α -phosphonates were extremely resistant to hydrolysis under conditions which gave complete hydrolysis of the acyloxyethylphosphonates (or ethyl laurate) at the carboxylic ester. (b) Concentrated Acid.—Three triethyl α -phosphonates were refluxed for 18–24 hr. with a large excess of 20–35% hydrochloric acid. The reaction mixture was transferred to an evaporating dish and evaporated to dryness. The crude residues from the hydrolysis of triethyl α -phosphonostearate and -laurate were hard, brittle solids, m.p. 125–130°; the residue from triethyl α -phosphonobutyrate was a hygroscopic semi-solid. The neutralization equivalents found (thymolphthalein indicator) were, respectively, 129, 101 and 58 (calculated for the tribasic acids, R—CH—CO₂H,

но—р—он

122, 94 and 56). Thus, essentially complete hydrolysis occurred. (c) Dilute Alkali.—In a kinetic study it was shown that one equivalent of base was consumed in about 1 hr. The following hydrolysis-isolation procedure was, therefore, employed to obtain the α -diethylphosphonocarboxylic acid: approximately 0.5-1 g. of triethyl α -phosphon-

ate (accurately weighed) was refluxed for 1 hr. with exactly 25 ml. of 0.2 N KOH in aldehyde-free 95% ethanol. The excess alkali was back titrated with 0.1 N HCl (phenolphthalein indicator) which permitted calculation of the saponification equivalent of the α -phosphonate, if desired. A few ml. of concentrated HCl was then added and the reaction mixture was evaporated to dryness. The residue was washed several times with ethyl ether and the combined ether solutions were filtered. Evaporation of the ether from the filtrate yielded the α -diethylphosphonocarboxylic acid, on which the neutralization equivalent was then determined. The saponification equivalents of the triethyl α -phosphonates and the neutralization equivalents of the α -diethylphosphonocarboxylic acids prepared from them are given in Table III.

Sulfenyl Carboxylates

BY ROBERT E. PUTNAM AND WILLIAM H. SHARKEY

RECEIVED JUNE 27, 1957

The synthesis of a number of sulfenyl carboxylates is described. These compounds are, in general, quite unstable, and preliminary evidence indicates that they decompose to give free radicals in a manner similar to peroxides.

Although amides, esters and acid halides of sulfenic acids have been known for a number of years,¹ the only example of a sulfenyl carboxylate that has been reported is 2,4-dinitrobenzenesul-

pane to form 2,4-dinitrophenyl 2'-nitro-2'-propyl sulfide also has been disclosed.³

Since sulfenyl carboxylates may be considered to be mixed anhydrides of sulfenic and carboxylic acids, they might be expected to undergo many of the reactions of anhydrides. In addition, the presence of a sulfur-oxygen bond suggests that these compounds may undergo radical reactions in a fashion similar to peroxides and disulfides. Accordingly, a study of the preparation and properties of a number of sulfenyl carboxylates was made in this Laboratory.

The carboxylates investigated (see Table I) were prepared by a modification of the method employed by Havlik and Kharasch² in the synthesis of 2,4-dinitrobenzenesulfenyl acetate. A finely divided silver carboxylate was stirred at room temperature with a solution of the appropriate sulfenyl halide in methylene or ethylene chloride. The sulfenyl carboxylates formed rapidly and, in the most favorable examples, were obtained in yields of 75–92% (compounds 1, 2 and 3, Table I).

The most striking property of this class of compounds is the tendency of its members to undergo spontaneous decomposition. Of the compounds prepared, only 2,4-dinitrobenzenesulfenyl benzoate proved to be stable indefinitely at room temperature. The thermal stability of the carboxylates seemed to be proportional to the electron-withdrawing ability of the groups attached to sulfur. Thus, 2,4-dinitrobenzenesulfenyl acetate and benzoate and trichloromethanesulfenyl benzoate were all stable enough to allow purification and identification. On the other hand, 1-anthraquinone-, 2-nitrobenzene- and 4-nitrobenzenesulfenyl acetates, although stable at -20° , decomposed so rapidly at room temperature that elemental analyses could not be obtained. Benzenesulfenyl and pentachlorobenzenesulfenyl benzoates were the least stable of the carboxylates prepared. These compounds decomposed at an appreciable rate even at -20° . The carboxylates were found to exhibit a characteristic infrared absorption band in the region 1710-1780 cm.⁻¹, and this band was used to identify those compounds for which analytical data could not be obtained. It is in-

(3) J. L. Cameron and N. Kharasch, U. S. Patent 2,671,113, March 2, 1954.

teresting that 1700-1800 cm.⁻¹ is the region in which carboxylic anhydrides exhibit strong carbonyl absorption in the infrared.

The nature of the decomposition of sulfenyl carboxylates is not known with certainty. The two most likely modes of decomposition are disproportionation to a sulfenic anhydride and a carboxylic anhydride (1) and homolytic cleavage of the -S-O- bond to form free radicals (2).

l		+	• •
Ô	Ō	$R'-R' + CO_2$	

Preliminary evidence points to path 2 as the mechanism of decomposition. During the determination of the infrared spectra of benzenesulfenyl benzoate and pentachlorobenzenesulfenyl benzoate, it was noted that the carbonyl band of the carboxylate gradually disappeared and was replaced by a band characteristic of the carboxylic acid from which the carboxylate was derived. From the resulting mixtures it was possible to isolate the disulfides and carboxylic acids which would be expected according to path 2. In addition, pyrolysis of 1-anthraquinonesulfenyl acetate in vacuo at 150° led to bis-(1-anthraquinonyl) disulfide and acetic acid as the only identifiable products. It is probable that compounds of the type R-R and CO_2 were also produced but they were not identified.

As is the case with sulfenyl halides,^{1,4,5} sulfenyl carboxylates are rapidly decomposed by aqueous base giving complex mixtures of disulfides, sulfenic anhydrides and salts of sulfinic acids. Sulfenyl carboxylates have two potential sites for attack by nucleophilic reagents, at the sulfur atom and at the carbonyl group. Attack at either position by aqueous base would yield a sulfenic acid which would then undergo further reactions. Reaction with other nucleophilic agents, such as alcoholates, would be expected to give a sulfenic ester or a carboxylic ester, either of which would be sufficiently stable for isolation.

Investigation of this reaction has shown the primary site of attack to be the carbonyl group.

Thus, addition of a solution of 2,4-dinitrobenzenesulfenyl acetate in methylene chloride to methanolic potassium hydroxide at -80° gave as the major products methyl acetate and a deep violet solid, which is thought to be the potassium salt of the hitherto unknown 2,4-dinitrobenzenesulfenic acid. Because of its instability this salt could not be isolated in pure form but analytical data on the crude, dry material corresponded to an empirical formula of $2[(NO_2)_2C_6H_3SOK] \cdot CH_3OK \cdot 3CH_3OH$. The properties of the material support this structure. The deep violet color is similar to that of the previously described salts of 1-anthraquinonesulfenic and 2-nitrobenzenesulfenic acids.^{6,7} When dissolved in deoxygenated water and acidified, the material lost its deep violet color and bis-(2,4dinitrophenyl) disulfide precipitated from the solution. A disulfide is one of the products to be expected from reactions in which sulfenic acids are intermediates.1,4,5

As mentioned previously, Kharasch² has described the addition of 2,4-dinitrobenzenesulfenyl acetate to cyclohexene to give a product of type I.

This reaction has been confirmed in this Laboratory, and, in addition, 1-anthraquinonesulfenyl acetate was added to cyclohexene to give a product $(R = 1-C_{14}H_7O_2, R' = CH_3)$ identical to that of Jenny⁸ who prepared it by reaction of silver acetate with 1-(2'-bromocyclohexylmercapto)-anthraquinone.

A brief study⁹ also was made of the behavior of sulfenyl carboxylates as photoinitiators for the polymerization of methyl methacrylate. As might be expected those carboxylates having nitro groups proved to be efficient polymerization inhibitors. However, both trichloromethanesulfenyl benzoate and benzenesulfenyl benzoate initiated the polymerization of methyl methacrylate when exposed to ultraviolet light, being considerably less active than 2-methoxy-2-phenylacetophenone¹⁰ and dibenzoyl disulfide.¹¹ It is interesting in this respect that esters of several sulfenic acids recently have been reported to be effective photoinitiators.¹²

Experimental¹³

2,4-Dinitrobenzenesulfenyl Acetate.—The following procedure is typical of that employed in the preparation of sulfenyl carboxylates. Temperatures as low as -20° were used successfully in the case of less stable members of the series.

- (12) G. H. Birum and R. J. Kern, U. S. Patent 2,769,777, Nov. 6, 1956.
- (13) All melting points are uncorrected.

To a solution of 11.8 g. (0.05 mole) of 2,4-dinitrobenzenesulfenyl chloride in 200 ml. of methylene chloride was added 16.7 g. (0.1 mole) of silver acetate. The slurry was stirred at 28° in the dark for 18 hr. The silver salts were removed by filtration and the filtrate was evaporated to dryness *in vacuo* (without heating). In this way there was obtained 11.1 g. (86%) of 2,4-dinitrobenzenesulfenyl acetate as a bright yellow solid which decomposed without melting at 85–90°. An infrared spectrum of the compound showed an "anhydride" carbonyl absorption band at 1780 cm.⁻¹.

Anal. Calcd. for $C_8H_6N_2O_6S$: C, 37.21; H, 2.34. Found: C, 37.40; H, 2.60.

Pentachlorobenzenesulfenyl Chloride.—A slow stream of chlorine (dried by H_2SO_4) was passed through a solution of 25 g. (0.09 mole) of pentachlorobenzenethiol in 500 ml. of refluxing carbon tetrachloride containing a few crystals of iodine for 5 hr. During this time a bright red color developed. Evaporation of the solvent *in vacuo* gave 26 g. (92%) of pentachlorobenzenesulfenyl chloride as a bright orange solid, m.p. 99–101°. One recrystallization from carbon tetrachloride gave long orange needles, m.p. 103– 104°.

Anal. Calcd. for C₆Cl₆S: S, 10.12. Found: S, 10.07.

This compound was used in the preparation of pentachlorobenzenesulfenyl benzoate (Table I).

1-(2'-Acetoxycyclohexylmercapto)-anthraquinone.—To a solution of 1 g. of 1-anthraquinone sulfenyl acetate in 30 ml. of glacial acetic acid was added 5 ml. of cyclohexene. The mixture was refluxed for 10 minutes and poured onto 200 g. of ice. The orange-yellow precipitate was removed by filtration. Recrystallization from absolute ethyl alcohol gave 1-(2'-acetoxycyclohexylmercapto)-anthraquinone as orange-yellow needles, m.p. 162-163°. A mixed melting point with an authentic sample prepared by the method of Jenny⁸ (m.p. 163-165°) showed no depression (162-163°). Decomposition of 1-Anthraquinonesulfenyl Acetate by

Decomposition of 1-Anthraquinonesulfenyl Acetate by Heat.—In a flask equipped with a thermometer extending nearly to the bottom was placed 5 g. of 1-anthraquinonesulfenyl acetate. The flask was evacuated and heated gradually to 150°. At about 130° a distinct color change from orange to yellow-green occurred. Volatile products were collected in a trap cooled to -70°. The reaction vessel was heated at 150° for 3 hr. The residue in the flask weighed 4.25 g. and proved to be mainly bis-(1-anthraquinonyl) disulfide as shown by identity of its infrared spectrum with that of an authentic sample. From the -70°trap there was obtained 0.6 g. of a liquid which was chiefly acetic acid (neutralization equivalent calculated 60, found 63.5).

Methanolysis of 2,4-Dinitrobenzenesulfenyl Acetate.— To a solution of 7.8 g. (0.03 mole) of 2,4-dinitrobenzenesulfenyl acetate in 300 ml. of methylene chloride, cooled to -70° and kept under a blanket of nitrogen, was added dropwise a solution of 1.6 g. (0.03 mole) of potassium hydroxide in 15 ml. of anhydrous methanol. During the addition (about 15 minutes) the mixture was stirred vigorously and stirring was continued for 30 minutes longer. By this time a large quantity of deep violet solid had precipitated. The mixture was filtered carefully under nitrogen at -50° . After washing with ether and vacuum drying, there was obtained 6.3 g. of a deep violet powder. The filtrate had a strong odor of methyl acetate, and an infrared spectrum confirmed the presence of appreciable quantities of this ester. No attempt was made to isolate the ester quantitatively because of the large volume of methylene chloride present.

Analysis of the violet solid after drying showed it to have an empirical formula of $2C_6H_8N_2SO_5K \cdot CH_3OK \cdot 3CH_3OH$.

Anal. Calcd. for 2C₆H₃N₂SO₆K CH₃OK 3CH₃OH. 28.48; H, 3.14; N, 8.30; S, 9.50. Found: C, 28.12; H, 2.66; N, 8.26; S, 9.55.

When the salt was allowed to stand in air it rapidly decomposed, losing its violet color in the process. Similarly, it proved to be quite unstable in ordinary distilled water. However, a solution in deoxygenated water was stable for several hours. For this reason an attempt was made to isolate the free sulfenic acid by acidification of its salt in a completely deoxygenated system.

To 1 g, of crude potassium salt dissolved in 200 ml, of deoxygenated water was added 0.5 N HCl (made up in deoxygenated water) until no further color change was appar-

⁽⁶⁾ K. Fries, Ber., 45, 2965 (1912).

ent. The cloudy, orange-yellow solution was cooled to 0° and filtered. In this way there was obtained 0.3 g. of bis-(2,4-dinitropheny) disulfide as a yellow powder (structure shown by identity of its infrared spectrum with that of an authentic sample). The filtrate was extracted with ether, and the ether layer dried over anhydrous sodium sulfate.

Evaporation of the solvent yielded 0.24 g. of a brownish acidic solid that could not be identified positively. No evidence for the presence of 2,4-dinitrobenzenesulfenic acid was obtained.

Allylic Rearrangements. XXXIX. The Reaction of α, α -Dimethylallyl Chloride and γ, γ -Dimethylallyl Chloride with Thiourea and Substituted Thioureas¹

BY J. M. RULE, I. J. WILK, T. I. WRIGLEY AND WILLIAM G. YOUNG

RECEIVED JULY 19, 1957

The reactions of α, α -dimethylallyl chloride and γ, γ -dimethylallyl chloride with thiourea in acetone both follow secondorder kinetics. The tertiary allylic chloride undergoes an abnormal Sn2' displacement while the primary chloride undergoes a normal Sn2 displacement. The same product γ, γ -dimethylallylisothiouronium chloride, was obtained in both cases. *sym*-Diphenylthiourea behaved similarly, but fully substituted thioureas did not undergo reaction with either the primary or the tertiary allylic chloride.

Introduction

Two mechanisms of bimolecular nucleophilic substitution are available to allylic compounds, the normal displacement, SN2, and the abnormal displacement SN2'. Several examples of the latter process are known and have been reviewed recently in detail.² For example, it has been shown by de la Mare³ that nucleophilic attack on α, α -dimethylallyl chloride (I) by thiophenolate ion yielded only the product due to an abnormal SN2' displacement. Allylic halides are known⁴ to react with thiourea to form thiouronium halide salts which can be hydrolyzed to thiols by aqueous alkali. The purpose of the present work was to examine the reaction of pentenylallylic chlorides with various thioureas.

Results

When α, α -dimethylallyl chloride (I) was treated with thiourea in acetone at 25° an abnormal SN2' displacement resulted and γ, γ -dimethylallylisothiouronium chloride (II) was obtained in 80% yield. This salt was also the sole product from the reaction of γ, γ -dimethylallyl chloride (III) with thiourea, and after ozonization and suitable decomposition of the resulting ozonide it afforded acetone in high yield.

Similarly, treatment of α, α -dimethylallyl chloride (I) with N,N'-diphenylthiourea (IV) gave only the abnormal product γ, γ -dimethylallyl-N,N'-(1) This work was supported in part by a grant from the National Science Foundation.

diphenylisothiouronium chloride (V) which was also isolated from the reaction of the primary chloride III with IV. No reaction was detected between N,N'-dibutylethylenethiourea and α, α -dimethylallyl chloride (I). In order to lower the activation energy the primary chloride III was substituted for I, but still no reaction was observed. Similarly, neither N,N,N',N'-tetramethylthiourea (VI) nor N,N'-dibenzoylthiocarbanilide (VII) would react with γ, γ -dimethylallyl chloride (III) in acetone.

A kinetic study of the reaction of the primary and tertiary allylic halides I and III with thiourea, followed by alcoholic base titration of the acidic components present, indicated both reactions to be second order. Rate constants were calculated from the integrated form of the usual second-order rate expression,⁵ as given in equation 1.

$$k_2 = \frac{2.303}{t(b-a)} \log \frac{(b-x)}{(a-x)} \frac{a}{b}$$
(1)

Where x is the amount of allylic halide reacted in moles/1., b is the initial concentration of thiourea in moles/1., a is the initial concentration of allylic halide in moles/1. and t is the time, in minutes, elapsed from zero time. The rate was followed by titration with alcoholic sodium methoxide of the acidic isothiouronium salts formed. Rate constants are listed in Table I.

TABLE I

Second-order Rate Constants for the Reaction of α, α -Dimethylallyl Chloride and γ, γ -Dimethylallyl Chloride with Thiourea in Acetone

Isomer	RC1ª	Thiourea ^a	Temp., °C.		k_2b
