Since gem-difluoroolefins have a unique reactivity with nucleophiles, their synthetic utilities as building blocks for fluorinated and nonfluorinated compounds have recently been greatly explored.1 Most of these works have focused on the stereochemical aspects of the addition-elimination products,² proton exchange reaction of carbanion generated via nucleophilic addition pathway in alcoholic media,3 and ease of β-defluorination of resultant carbanion,⁴ and only limited work has been directed to the synthetic application of gem-difluoroolefins.⁵ For example, the reaction of 2,2-difluorovinyl ketones with carbon or heteroatom nucleophiles afforded α,β-unsaturated ketones or α-oxoketene acetals via successive replacements of the two fluorines^{5a} and the reaction of gem-difluorinated ketene dithioacetals with a bidendate sulfur nucleophile has been reported. 56 Recently, we reported an efficient method for the synthesis of 1phenylthio-2,2-difluorostyrene (1a), as a new type of gem-difluoroolefin, from 2,2,2-trifluoro-1,1-bis(phenylthio)ethylbenzene⁶ and the synthetic application of this compound for the preparation of various types of heterocyclic ketene acetals⁷ and 4H-pyran-4-one derivatives⁸ via exocyclization of 1a with bidendate nuclophiles. In our continuing studies on the chemistry of 1a toward bidendate nucleophiles, we found that 1a reacted with dianions of β-enamino ketones to give monosubstituted products or pyridinone derivatives, depending on the type of \beta-enamino ketone. Especially, this reaction provides a new methodology for the formation of pyridinone derivatives which are very important framework for the antibacterial agents.9 In this communication, we wish to report a preliminary result of this reaction.

When the reaction of 1-phenylthio-2,2-difluorostyrene (1a) with dianion of 4-(N-methylamino)pent-3-en-2-one (2a), generated by the treatment of 2 with 4 equiv. of LDA at -78 °C, ¹⁰ was carried out at -78 °C, only monosubstituted product 3a (E:Z=78:22) was obtained in 76% isolated yield. No pyridinone derivative was detected. However, the reaction of 1a with dianion of 2 at -78 °C, followed by warming to 25 °C, provided the monosubstituted product 3a¹¹ and pyridinone derivative 4a¹² in 74% and 6% isolated vields, respectively. This result indicates that the monosubstituted product 3a does not easily undergo exocyclization under the employed reaction conditions, which is quite contrast to the case of the reaction of 1a with dianion of 1,3-diketone.8 The use of 2 or 3 equiv. of LDA to generate the dianion of 2 did not complete this reaction, while the starting material was always recovered. The reactions of other types of 1-substituted 2,2-difluorostyrenes 1bf with 2 under the same reaction condition afforded only monosubstituted products 3. The results of these reactions were summarized in Table 1. The assignments for isomers

^a Isolated yields. ^b All products are E- and Z- isomeric mixtures.

of **3a** were based on the chemical shift for vinyl fluorine in ¹⁹F NMR and allylic protons in ¹H NMR. Generally, the allylic protons which are arranged to the same side of phenylthio group (E-isomer) are more deshielded than those of Z-isomer.¹³

In contrast to the reaction of 1a with dianion of 2, the reaction of 1a with dianion of 4-(N-phenylamino)pent-3-en-2-one (5), which was generated by the treatment of 5 with 4 equiv. of LDA at -78 °C, under the same reaction condition afforded pyridinone derivative 6a and the monosubstituted product 7a in 43% and 28% isolated yields, respectively. The similar reactions of dianion of 5 with several types of 1-substituted 2,2-difluorostyrenes 1b-d also provided a mixtures of **6b-d** and **7b-d** in moderate yields. When dianion of 5 was reacted with 1e under the same reaction condition, however, pyridinone derivative 6e was isolated in 18% yield. This reaction gave a complex reaction mixture and other product 7e could not be isolated. The results of these reactions were summarized in Table 2. A plausible mechanism for the formation of 6 can be proposed as shown in Figure 1. Initial attack of more nucleophilic carbon atom in the dianion[I] on the starting material 1 resulted in the formation of intermediate[II] via addition and β-defluorination. Exocyclization via nucleophilic attack of nitrogen on fluorovinyl carbon atom in intermediate[II], followed by β-defluorination to provide intermediate[III] which gave the final adduct 6 via 1,3-hydrogen shift. This 1,3-hydrogen shift can be rationalized by generation of enolate via a reaction of intermediate[III] with fluoride, followed by allylic rearrangement which is favorable for the formation of resonance hybrided 4-pyridinone.

Figure 1. A plausible mechanism for the formation of 6 from the reaction of 1 with 5.

A typical reaction procedure is as follows. To a tetrahydrofuran (10 mL) solution of 4-(N-phenylamino)pent-3-en-2one (0.175 g, 1.0 mmol) was added LDA (4.0 mmol) at -78 °C, and the reaction mixture was stirred at -78 °C for 30 min. under argon atmosphere. 1-Phenylthio-2,2-difluorostyrene (0.248 g, 1.0 mmol) was added dropwise at -78 °C and the reaction mixture was stirred at -78 °C for 2 hours, followed by warming to room temperature. The reaction mixture was poured on ice water and extracted with ethyl acetate. The ethyl acetate solution was dried, concentrated in vacuo and the residue was chromatographed on SiO₂ column. Elution with a mixture of hexane and ethyl acetate (1:2) provided N-phenyl-2-methyl-6-(1-phenylthiobenzyl)-4H-pyridinone (6a) (0.165 g, 43%). 6a: mp 198-199 °C; ¹H NMR (CDCl₃) δ 7.95 (m, 1H), 7.88 (m, 1H), 7.60 (m, 1H), 7.48 (m, 1H), 7.32-7.20 (m, 8H), 7.05 (m, 2H), 6.86 (d, J=1.2 Hz, 1H), 6.79 (d, J=1.1 Hz), 5.06 (s, 1H), 2.11 (s, 3H); MS, m/z (relative intensity) 383 (M⁺, 13), 274 (100), 246 (36), 109 (10), 77 (29); IR(KBr) 3400, 1650,

1560, 1480, 1360, 750, 690 cm⁻¹.

E- and *Z*- mixture of 2-fluoro-1-phenyl-6-phenylamino-1-phenylthiohept-1,5-dien-4-one (**7a**) (0.113 g, 28%) was obtained as a minor product. **7a**: *E*-isomer: yellowish oil; 1 H NMR (CDCl₃) δ 7.65 (bs, 1H), 7.40-7.00 (m, 15H), 5.60 (s, 1H), 3.92 (d, J=21.9 Hz, 2H), 2.04 (s, 3H); 19 F NMR (CDCl₃) δ -86.0 (t, J=23.2 Hz, 1F); MS, m/z (relative intensity) 403 (M⁺, 1), 383 (1), 274 (8), 246 (4), 160 (100), 118 (11), 109 (5); IR (neat) 3000, 1590, 1560, 1480, 1530, 1320, 1260, 740, 680 cm⁻¹. *Z*-isomer: yellowish oil; 1 H NMR (CDCl₃) δ 7.62 (bs, 1H), 7.42-7.05 (m, 15H), 5.56 (s, 1H), 3.34 (d, J=21.9 Hz, 2H), 2.08 (s, 3H); 19 F NMR (CDCl₃) δ -85.5 (t, J=23.2 Hz, 1F); MS, m/z (relative intensity) 403 (M⁺, 1), 383 (1), 274 (8), 246 (4), 160 (100), 118 (11), 109 (5); IR (neat) 3000, 1590, 1560, 1480, 1530, 1320, 1260, 740, 680 cm⁻¹.

Enantioselective Synthesis of a trans-Hydrindane System for the Preparation of Vitamin D Metabolites[§]

Gilbert Stork* and Choon Sup Ra[†]

Department of Chemistry, Columbia University, New York, New York 10027, USA Department of Chemistry, Yeungnam University, Kyongsan 712-749, Korea Received November 15, 1996

Vitamin D metabolites and their analogs are receiving an intense attention due to their medicinal and therapeutic importances.1 trans-Hydrindane system constitutes the C/D ring synthon of these vitamin D compounds and continuous efforts have been made to develop new methods for constructing this structure. Approaches based on Lythgoe's methodology² via a convergent Wittig coupling of the Aring fragments and this bicyclic C/D-ring system remain particularly attractive in the synthesis of various vitamin D related analogs. Hoffmann-LaRoche group's synthesis³ of 1α, 25-dihydroxycholecalciferol (calcitriol), a medicinally active vitamin D₃ metabolite, is the classical example employing this strategy (Scheme 1).

Control of vicinal stereochemistry is very important in constructing this trans "angularly methylated" hydrindane and much effort has been directed to this area. For the enantioselective synthesis of angularly methylated hydrindanes, various routes have been devised including intramolecular Diels-Alder methodology, o-quinodimethane strategy, chiral auxiliary induced asymmetric polyene cyclization,6 Mukaiyama-Michael conjugate addition, use of β-sulfonyl vinyl ketone,8 in addition to Uskokovic approach3 using a

known asymmetric ketoacid.9

Here we report a new enantioselective synthesis of functionalized trans-hydridanone 1¹⁰ based on the highly stereoselective epoxide cyclization reaction with carbanions. 11 Our synthetic plan is highlighted in Scheme 2.

The preparation of 7, which served as the substrate for the intramolecular allylic epoxide cyclization was made starting from ε-caprolactone 2. Saponification of ε-caprolactone followed by Swern oxidation¹² of the resulting ester alcohol afforded ester aldehyde 3 (77%). Two-carbon homologation to aldehyde functionality by Wittig reagent¹³ gave 4 (79%) as a mixture of two isomers ((Z)-4:(E)-4=85:15). Methylation of this ketal ester 4 (61%) and subsequent ketal hy-
